tions and detail, see Bib (385, 403). Crew for a drag-line excavator lo
a sluice consists of an operator, a fireman and 2 to 4 men on the track

122. Hydraulic Mining or Hydraulicking (See also A

Term "Hydraulicking" is applied to the excavation of gravel ban
water thrown under pressure from nozzles. The method was invent
1852, by E. E. Mattison; see Bib (391) for history of its development.

General plan of work. Water is impounded in reservo
from streams, and conducted in ditches, flumes, and pipes to ar
above the placer and thence to the working face through pi
terminate in GIANTS or MONITORS (Fig 586), by which the direct
controlled. The gravel is broken down partly by direct impa
and partly by undercutting banks and forcing them to cave.
away from the face (usually in bedrock ditches), carrying the g
a sluice leading to a dump; the giants are often used to "pip
into the sluice. As the face is washed away, the bedrock cuts
advanced toward it. Some cemented gravel banks require
they can be disintegrated by water (see Bank blasting, below).

Details of water supply and methods of opening and advancing worki
ment of pipe lines, giants, sluices, etc, vary with local conditions; t

Working season is often limited by climate or water su seasons vary from 100 to 120 days. Where climate permits co water is rarely available the year around, even with reservoirs flood waters and melting snow. Length of season, proper scal annual returns, and capital required, are closely related.

Summary. Requirements for successful large-scale work a fied completely. Adequate amounts of gravel, gold, water ar feasible working season are absolute essentials. Lack of natur and dumproom generally prohibits extensive hydraulicking, l times be met by use of elevators (Art 125); the latter add an capital cost which may or may not be prohibitive.

Miscellaneous data on equipment. WATER SUPPLY is usually item; see Sec 38 for general data on rainfall, runoff, reservoirs, ditches, Flumes are preferable to ditches in all doubtful ground; both should turnouts and sand gates. Distributing reservoirs are required near avoid wastage when giants are turned off; their number, size, and im with the length of ditch and number of shut downs that occur. Almo expenditure is justified for preventing breaks in the supply system; c is essential to large output and low costs. A PRESSURE BOX (penstoc upper end of pipe leading to giants, to catch floating leaves and sticks, se and keep air out of the pipe; for details, see Bib (391, 406). A single able if it will supply all the giants; it must be carefully anchored and d in as direct a line as possible. Air valves are necessary to prevent colla it is emptied. Each branch leading to a giant should have a gate.

Operation of giants. Banks are usually broken by undercutting an ing faces should be kept square and advantage taken of corners. Na concave faces are avoided, as workmen are constantly menaced by Water should be turned away from a bank that is about to cave, othe caved material may reach the giants and men. Water cuts fastest whe a bank at an oblique angle. Banks shaped as in Fig 582, with giants nose, allow effective use of water and reduce danger from caves, as the l at right angles to the face and not toward the giant. Some Alaska creek gravels 15 to 50 ft deep by setting the giant on top of the bank stream, but the duty of water thus obtained does not indicate a high With 1 giant, part of the bank is caved, then with a larger nozzle the falle to the sluices. With 2 or more giants, their time is apportioned be sluicing. BOOSTER GIANTS may be used to drive gravel across flat bed

Number of giants depends on size of working face, character of gra amount of water. Practice tends towards use of a small number of la than a larger number of small ones; the former cut faster and save l placed to command as much of the face as possible, to work advanta bined attack on one point, and as near the face as is safe (406). For be 2 giants and 2 working faces are required, so that hydraulicking ma face while boulders are being cleared away from the other (394).

Height of face for economical work is normally limited to a max higher banks are usually worked in benches. Conditions allowing high water pressure, compact gravel that does not "run" when caved, and Where the bottom layer of a high face is tough, the upper gravel ma enough to allow the giants to be moved closer to the face and exert m

Bank-water (bank-head or bye-water) is a term applied to strea pit in ditches, not under pressure. Bank-water is allowed to run ov in disintegrating clayey gravel, thawing frozen ground, moving gravel maintaining a steady flow through it.

Bedrock cuts or ditches are a continual and sometimes serious so most hydraulic mines; in some early Cal mines, they reached 60 ft de case shown in Fig 582, 4 men were constantly employed in extending When much clay is present, more branching bedrock cuts are requ

Note. 75% dynamite cost 30¢ per lb del'd at mine. No boarding house expense appears separately, as this was charged directly to the different operations each month and is therefore included in labor charges. General operation includes supplies, wages of teamsters, blacksmith, and other expense not directly chargeable to either pit. This expense was equally divided between the pits at end of season, except for such supplies as were directly charged to either pit. General expense includes traveling, office, and other incidentals, not directly connected with actual operation. Ditch maintenance includes all expense on ditches for repairs, etc; but not the wages of ditch-tender, as this was charged to No 1 pit. Royalties, rentals, etc, include Gov't tax on gold. Last 3 items were divided between the pits at end of season. Above costs do not include charges for redemption of capital or deprec of plant. Much more detail is given by Hughes, Bib (411).

50	30d	Top rails to posts and sides .	50	30d

lows: 420 ft lumber @ $30 per M, $12.60; 36 blocks @ @ 4¼¢, $0.64; labor @ $1 to $2.50, $2.50.

Trinity Co, Cal (415). 600 to 700 miner's in wash 500 cu nd braces are bolted together; sills are mounted on skids nd beveled at each end. Boxes are moved over bedrock to lock riffles are 11 in or 18 in sq by 10 in deep; riffle strips, out $20; the company has a sawmill.

ine, Trinity Co, Cal (415). Sluice is laid in an 8 by 8-ft es are of 1.5 by 6-in, 1.5 by 4-in, and 4 by 5-in pieces. Riffle 11 in to 18 by 18 in sq. Side liners of 2 by 10 and 2 by 6-in sticks, 2 by 2 in by 5 ft. 500 bd ft of lumber used per box ; 525 bd ft for blocks. Cost per box: lumber, $16; blocks, ncludes nails and labor for handling and placing.

ine, Siskiyou Co, Cal (416). Sluice is at head of an hydrau- t c-c. 12 in sq blocks used for riffles, also rails and trans-

efly at the head of hydraulic elevators (Art 125). They are stance and are easily bolted together; their cost is prohibitive for dredges (Art 126) are an exception).

STANFORD LIBRARIES

Curves should be avoided if possible; they increase friction a duce velocity of the water, and if sharp cause splashing.

Sluices are curved by making small deflections at successive joints. says a 5-in "swing" is the max permissible for a 12-ft box; if a sharper tur use a 4-in swing on a 6-ft box, or 3.5-in on a 4-ft box. Curves should be ends, and the outer edge of the boxes elevated from ⅛ to ⅜ in per ft o Grade of the sluice should also be steepened at curves; an increase of as is desirable on short turns. Bowie (391) gives further data on curves, rela and turn-out sluices. These work well on steep grades, but require car flat grades at connections with main sluice; otherwise gravel collects a

grades were only 2.75 to 4 in per 16-ft box. Originally, the opening at point was 14 ft wide; there was a 1.5-in drop between main and turn-out sluices, was swung 4 in per 16-ft box; it worked satisfactorily. On increasing the sw boxes adjacent to the junction choked, and the discharge had to be wid It was found here that, in a 200-ft swing on a 2% grade, the greatest poss 16-ft box was 8 in for a 4-ft sluice; but the curve could be increased in pro grade. At the turn-in and turn-out a board must be placed diagonally ac sluice, to concentrate the discharge and prevent formation of bars.

Duplicate sluices are sometimes installed to avoid delays; one while the other is running; both usually empty into one tail sluice

In sluicing tin-bearing gravels, there may be enough concentrate to fill short time and require frequent clean-ups; in such circumstances, du allow continuous operation.

Bulkheads. The head end of a sluice for hydraulicking is u out by building diverging bulkheads (wing dams) on each side; collecting gravel and water as they flow back from the face, and ass fallen gravel into the sluice.

H. L. Mead, in 1913, stated that the sluice mouth at La Grange, Cal, is 18 ft high; a heavy bulkhead of this height is built out from both sides generally work in pairs, first cutting down the bank and then swinging aro the fallen gravel toward the sluice and adding water to it; very heavy mate be washed into the sluice. The high bulkhead and high sides of the sluice allow gravel to build up and increase the grade; this, with the above meth starts material down the sluice with a high velocity and increases its capac

ed on small sluices in Alaska as a puddling or dump box, l. In it, sticky clay and mud are broken up and large stalled for the latter purpose alone in shoveling-in, if the ice fork effectively. Mud boxes have an apron 8 or 10 ft a slope of or derrick r scrapers pron and are set on 2 ft) than le, block, h of the 6 in wide ft and in ton (390) acity and ie cost of avel and ld-saving eir opera- l variable for some

y expressed in terms of the fall in inches per sluice not given, it is understood to be 12 ft. Thus, a 5 in per 12 ft. Grades should be uniform; flat r of the whole sluice; riffles and linings in steep and the flow must be stopped for replacing them. aver conditions, 6 to 7-in grades are satisfactory. p, grades as flat as 2.5 or 3 in per 12-ft box have nd earth. Flat grades reduce the duty of water of stones that can be sent through the sluice, and handling boulders. Lack of grade may be com- increasing the amount of water; conversely, steep water supply. Grades over 13 to 14 in per 12 ft d by topography, as the resulting velocity of flow rse gold.

es worked on grades of 10 to 24 in per 12 ft. Water was e sluiced (391). See Table 91.

luice grades depend largely on the kind of gravel; steep flat, sub-angular, or cemented gravel, and when much des may be flatter, and a larger duty is obtained with a ter, when sluicing a mixture of large and small gravel. s stir up fines and keep them in suspension.

l be sufficient to disintegrate the gravel and free his is accomplished in 100 to 300 ft. Crude shov- often use only 3 to 6 boxes; lengths, 36 to 72 ft to save very fine gold. DROPS (vertical falls) may aphy allows) to break up cemented gravels and

a sluice so long as the yield from the lower boxes exceeds them. Velocity of flow largely determines the minimum es; hence, a greater length than is necessary to disinte- ort sluices with drops and undercurrents (Art 124) are than long sluices without them. Very long sluices may

STANFORD LIBRARIES

be needed to transport gravel to dumps; their lower parts are called TAIL-SLU examples of lengths see Tables 94, 99 and under Cost data, Art 122.

Cross-section of sluices is proportioned to amounts of water a and to the velocity of flow, which in turn depends on the grade. For first cost and wetted perimeter (hence for minimum frictional resis max discharge for a given cross-sec) the sluice width should be about depth of stream, as in flumes (Sec 38, Art 15); it may be impossible this ratio in large sluices. Depth of water should be sufficient to the largest stones. Width of sluice is adjusted to depth and grade, quired capacity. Fine gravel containing fine gold should have ver wide sluices, on steep grades (see Undercurrents (Art 124)). The ten riffles to pack increases with depth of stream, which is usually 6 to 1

To reduce first cost, and facilitate cleaning out and replacing riffles, th sides of a sluice should not exceed 1.3 to 1.5 times the depth of stream. Fo deep cuts in firm ground, sides may be lower than for those on or above the s surface sluices clog and overflow, much of the gravel in them above point must be shoveled out (406).

Water required. The only data available are given under Duty in hydraulicking, Art 122; these data are unsatisfactory, as the cutti ity of giant water may not equal its sluicing capacity.

The water used in a small sluice for shoveling-in (Fig 589) is known as a " sl irrespective of its quantity; it varies from 30 to 60 miner's in for sluices 10 to set on grades of 6 to 8 in per 12-ft box. In British colonies this term means cu ft of water per sec (394).

Calculations of sluice grades, cross-section, velocity of flow, etc, canno accurately, because the complex relationships between the factors are not wh and few experiments have been made to determine the necessary empirical

40	Carries sand as coarse as linseed
60	Moves fine gravel
120	Moves pebbles of 1 in diam
180	" " of egg size

Most authorities suggest so cation of Chazy's formula, 11, as a basis. For exampl (394, 388, 417).

The author's calculatio Kutter's formula (Sec 38), sluices where all necessary available, show values fro 0.04. Calculations should against actual operations under similar conditions; Tables in Art 122, 123 a Geike gives the above data on velocity of streams required to move materia ent sizes (418). Somewhat smaller velocities suffice for sluices.

Van Wagenen (417) states that a veloc of 200 ft per min is necessary to move pebbles the size of an egg, 320 ft for stones of 3 to 4 in diam, 400 ft for boulders of 6 to 8 in diam, 600 ft for boulders 12 to 18 in diam. G. K. Gilbert's experiments on stream and flume traction are also suggestive, Bib (419).

(*a*) Depth of flow, 6 to 7 in. (*b*) Depth of flow, 10 in. (*c*) Height of side, in this and following examples, is 0.5 to 0.75 width of sluice; depth of flow, 0.33 to 0.5 of clear inside depth of sluice. Duty of water (Art 122) must be known or assumed in designing a sluice for a given amount of gravel.

that when worn they may be turned as requir
smoothest surface; the side of the square is a
of the sluice width. It is usual to set blocks in
to break joints, because longitudinal cracks e
and force earlier renewals.
At a few mines, better gold recovery is claimed for a pavement in which joints are broken as above, but longitudinal spaces are also left between the blocks of each row (390). Blocks are held in place by the side lining and riffle strips. Each strip is nailed to a row of blocks with headless wire nails, which are not driven home but project from 0.5 to 0.75 in. The adjacent blocks are driven against these nails until they rest solidly against the riffle strip. For dimensions see examples following Table 99.

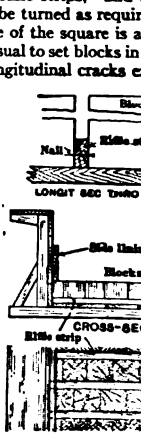

Fig 597. Bloc

The objection to block riffles is their rapid wear under heavy service; their life depends on quality of wood, sluice grade, character and quantity of gravel, and amount of water. Long-grained wood, which "brooms up," is best; hard wood is not desirable. On a given grade, the larger the ratio of water to gravel, the less the wear (391). Blocks worn to a thickness of 4 or 5 in are discarded, or used for lining the sides of sluices. Bowie gives followi early California mines (391) (see also Table 96, 97).

Locality	Width of sluice	Grade, in per 12 ft	Depth of blocks, in	Life of miner's
North Bloomfield.....	6	6.5	13	175 000
Manzanita mine.....	5	7.0	13	100 000
La Grange.....	4	3.0	8	100 000

At Manzanita mine, and also at French Corral mine where similar figures w poorer timber was used for blocks than at North Bloomfield. P. Bouery, i states that in 6-ft sluices at La Grange the life of 13-in blocks was 45 days to in the higher boxes lasted longest. On increasing the duty of water 40%, the decreased 60%, so that a clean-up was necessary every 17 days. Conseque expense, and limited supply of pine blocks, led to use of manganese steel rif Similar substitutions have been made at several large mines since 1910 (421

Longitudinal rail riffles (Fig 598) are of 20 to 40-lb RR rails, in leng usually set upside down and spaced 3 to 5 in or more apart by wooden or C-I

Dredging (Art 126).

Side linings are required to protect the sides of large sluices; also they often furnish a means of holding riffles in place.

Plank liners are common (Fig 597), 1-in for smaller sluices, 2 to 3-in for wide sluices with a large head of water. Where block riffles are used, worn blocks are placed on the sides; they serve for tail sluices, but are inconvenient where frequent clean-ups are necessary. See Fig 601 for rail linings. Height of side linings need not be more than 2 or 3 in above normal level of the stream of water and gravel.

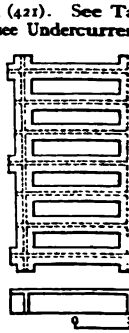

Fig. 604 (after

Undercurrents are intended to save fine gold which will not settle in the sluice. Fig 606 shows the North Bloomfield undercurrent, fairly typical for large Cal sluices; it is practically a wide sluice, set on a heavy grade at one side of and below main sluice.

Bowie gives following details: Across the main sluice, at some point can be made, is placed a grizzly, over which coarse material and some of th

sults were obtained in treating marine grav
ing fine shingle (425). The proper size of h
locality is a matter of simple experiment.
River, Idaho, a different form of Caribou ri
dercurrent has been used, in which the heavi
of the concentrates is drawn off continuou
holes in the sluice bottom. This allows th
of black sand containing valuable minerals
gold which require further treatment (426).

Operators disagree as to the use and
undercurrents. Where the gold is fine t
of evidence is in their favor, if they are
designed and cleaned up often enough to do efficient work. At La Ge
after riffles like those in Fig 602 had been installed, undercurrents were
as they clogged and the gold recovered did not pay cost of cleaning up

Use of mercury in riffles and undercurrents is quite general; an
easier to handle in clean-ups than fine gold; some gold, otherwise lost,
saved by amalgamation. Where much coarse gold occurs, mercury i
in a few boxes at the head of the sluice, to avoid the trouble and cost of retorting coarse gold amalgam.

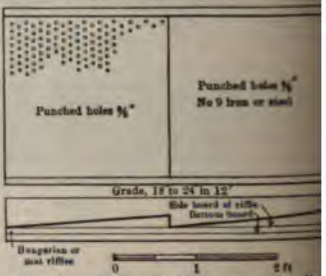

Fig 608. Caribou Undercurrent (after Pu

Sluicing begins with a small head of water, until all cracks and leaks are stopped. The water is then shut off and the riffles in the upper part of sluice and undercurrents are charged with mercury. More is added from time to time, as needed to keep a clean surface of mercury exposed. Amounts of mercury used vary widely; a common initial charge for large sluices is 2 to 3 flasks (76.5 lb each); for large undercurrents, 80 to 160 lb. Mercury must be clean and in charging all or spattering should be avoided; otherwise minute globules are formed which Loss of mercury is inevitable; it varies from 4 or 5% of the total amount us under poor conditions, averaging perhaps 10 to 15%; loss is least in well-l sluices, provided with undercurrents (391, 394).

Cleaning-up consists in removing the riffles and collecting the amalgam. Interval between clean-ups is made as long as possible, the delay they cause; often the lower parts of a sluice are cleaned once in a season. Clean-ups are required when worn riffles must be and when much gold has collected, as in the first few boxes of a sluice rich gravel; danger of theft often influences the frequency of clean-up

Cleaning-up begins at the sluice head, by removing a few riffles and turning flow of water. The concentrates are worked over with shovels or scoops, a slowly down the sluice bottom, the gold and amalgam lags behind the black and are scooped up into pans or buckets. The process is repeated in the section. See Bib (414, 391, 398).

125. Elevators

Elevators are employed to secure artificial dumproom at placers lacking ties for the disposal of tailing, and where conditions prohibit dredging.

Hydraulic elevators (Fig 609–611) are often used in connecti draulic mining. The excavated gravel, with the giant water and conducted in ground- or box-sluices to the foo vator, which delivers it to a sluice on the surfa the dump (385, 394, 390, 397). The surface slu short, with undercurre OF USE is i lacking s and dum having a cheap wate sure. De

worked range from a few ft to 90 ft; depths of 20 to 25 ft are favor allow considerable gravel to be mined from 1 set-up of the eleva excessive lift. Boulders (or buried stumps and timber) too large to the elevator increase the operating cost, as they must be blasted o derricks; if too numerous, they may prohibit elevator work. The h vator is inefficient and wasteful, but useful where the necessary water is available. Its CONSTRUCTION and OPERATION are shown by Fig 610.

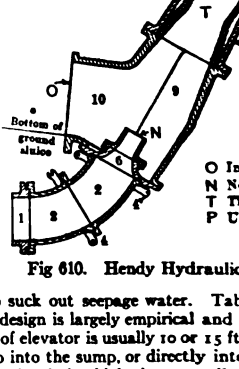

Fig 610. Hendy Hydraulic

Water under pressure is discharged upwards through nozzle *N*; in passing through the restricted throat area, *T*, it sucks in water, gravel, and air through intake opening *O*. The force of the jet elevates the aërated column of water and gravel through upcast pipe *P*, the upper end of which projects through the bottom of the first box of the surface sluice. To prevent spattering, this box is covered and is provided with a liner ("hood") which diverts the discharge laterally. The hood and throat take the most severe wear, and are usually of manganese steel; special steels may also be used for other parts. The upcast may be a riveted or welded steel pipe, with slip or flanged joints, depending chiefly on height of lift. The Evans elevator has an auxiliary suction opening on each side of the main intake, to allow air to enter the elevator if the main intake clogs; they may also be extended by pipes to low places on bedrock and used to suck out seepage water. Tab size and weight of elevators; data for their design is largely empirical and published by the makers. The SUMP at foot of elevator is usually 10 or 15 ft 4 ft deep (385). Bedrock sluices may dump into the sump, or directly int intake; the latter plan is best, as the suction head should be kept small. usually has a slope of 60° to 70°; the makers of the Evans elevator state best at 80°. Elevators are sometimes set vertically, or on slopes as flat as

Water required. The elevator nozzle water will lift from 0.5 to 1 × its of outside water. Hence, 50 to 66% of the pressure water available is as elevator, and the rest to the giants; the higher figure is conservative (no

Little Creek, Nome district, affords an interesting comparison wi Gravel is frozen, but bedrock is softer and flatter. A little more than hal are required to operate pits similar to those on Anvil Cr, but the combine and elevator water is only 1.09 cu yd.

River Bend Mine, Siskiyou Co, Cal; data by J. H. Theller, covering 6 tion in 1912 and 1913 (416). An old channel is worked, about 100 ft deep. Gravel is heavy, well rounded and contains boulders to 1 000 ll larger than 10.5-in diam is bulldozed. Gravel is hydraulicked with 2 No 2 using 350 in of water under a head of 90 to 100 ft. A Campbell ele with 3.5-in nozzle, 10.5-in throat, and 14-in upraise pipe at an angle of 70°. uses 375 in of water under an effective head of 325 ft; lift, 46 ft vert sump is 6 ft square at the collar, tapering to 4 ft at bottom. An aver of washed per day; duty of giant water, 1.19 cu yd per in. Seepage wate Working costs per cu yd, excluding administrative charges, are: foreman 2 freight, supplies, etc, 0.2¢; boarding-house, 1.4¢; maintenance and de deprec of plant and ditches, 1.5¢; total, 8¢ per cu yd.

Logan Mine, Waldo, Ore. From 15 000 to 30 000 cu yd of gravel wash with a total water supply of 1 600 miner's in; 4 giants are used, 2 in th stacking tailing. A 20-in hydraulic elevator, with 2 lifts, raises the gra large boulders and gravel is easily washed. Operating costs said to be a 4¢ per cu yd; this is a low cost, obtainable only under very favorable co

Swaziland, South Africa; data from J. J. Garrard (397). Tin-bearing aging about 18 ft deep, are worked. Records for 12 months' operation that 4 elevators, with an aver lift of 23.3 ft, took an aver of 73% of the w leaving 27% for the giants. Best month's work showed 60% elevator water; the worst, 84% elevator to 16% giant water; effic of elevator, 1(water supply was ample, its inefficient use was allowable. Working c including administrative charges, were about 12.5¢ per cu yd, covering at the rate of 466 cu yd per day. 61 native laborers were employed per s and 1 elevator; labor cost, 8.9¢ per cu yd. Elevator nozzle, 3.5 in; head on elevator water, 127 ft; consumption of nozzle water, 330 cu ft p

Box elevator. Knox and Haley (385) describe a home-made eleva cessfully by the North Fork Salmon River Mining Co, Cal. It consist lined box about 18 in sq, sloping about 50°, with a 5-in jet at the bott steel striking-plate at the top, immediately over the sluice. Height of lif operating head, about 250 ft. The water supply was excellent; about were required for the elevator. Boulders to 11 or 12 in diam were handled throat, everything being lifted directly by the jet. Capacity, about 1 00

Ruble or grizzly elevator consists of an inclined chute at an angle and 100 ft in length, including a 10-ft apron to make connection with apron fits closely between the walls of the main elevator chute; the latter long. The chute and apron are lined with 0.25-in steel side and ⅜-in Chute is about 8 ft wide, its walls tapering from 12 ft in height at the bo 4 ft at the top. For the first 20 ft of the incline, the bottom is solid. 70 ft consists of transverse grizzly-bars, 2.5 in apart, made of 2 by 6-in ti with 0.5-in steel straps. Underneath the grizzly is a steel-lined false b from upper end of the elevator to a sluice box, set at right angles to th directly under the lower end of the grizzly. The sluice, about 60 ft long on light trestles, is paved with Hungarian and pole riffles, consisting of 2 b shod with steel. If desired, the sluice can be covered and locked up. supported on 3 heavy stringers resting on trestle bents, which are moun skids, blocked up level from bedrock. It is moved with a winch and cabl

Operation: The elevator giant has its axis in a vertical plane passing thro line of the elevator and about 80 ft away from it. Wings, about 10 ft high scrap timber, are built out on either side, 1 wing extending to the bank; they on portable frames. The cutting giant works behind the elevator giant fallen gravel along the bank to the elevator wing, where it is picked up b giant and washed in small quantities at a time up the solid portion of the is taken to "boil out" the fines over the lower portion of the grizzly; o would be washed over the elevator top. 126. Gold Dredging

Introductory. A placer dredge is a scow carrying a mechanical
screening and washing plant, for mining subaqueous gravels. The
widely employed for INLAND DREDGING in California and elsewhere. T
on an artificial pond, usually supplied with water from an outside source;
supply is desirable, though pumping is often necessary. The dredge di
the pond and fills in the opposite side with washed tailing, thus carryir
it as it advances. Under suitable conditions the method is profitable fo
placers, otherwise unworkable. The modern efficient gold dredge has
since 1901; it may not yet have reached its limit of capacity and effect
The elevator bucket dredge is the only type described here, as it has p
seded other forms. Gold dredging is a subject of great detail; for a go
see (438, 437, 385); (409) contains a brief bibliography.

Requirements and limitations. Deposits suited to dredg
sive river bar and gravel-plain placers (Art 116), occurring chi
cally old districts. Requirements as to bedrock, character and
effect of boulders, cemented gravel and buried or standing tir
limits of dredging depth, water for dredge ponds, etc, are sum
117 and Sec 25, Art 7. See also under Cost and operating data,
considerations affecting choice of method and operation and de
are: CHARACTER OF GOLD. Very fine flaky gold, like that on th
Idaho, can not be profitably recovered by the present da
devices. Coarse gold sometimes modifies the form of the appa
GRADIENTS. Dredging is inherently applicable to large flat d
lack of grade prevents hydraulicking; small topographic irre
flat surface or bedrock gradients affect only the height of bank
water level. Some dredging has been done on grades as steep a
ing dams to maintain a pond (431). FROZEN GRAVEL must be
it can be dredged. Shallow gravels may be thawed by solar he
of removing muck or other covering; deep gravels require s
(Tables 121–123). FLOODS. Dredging in beds of torrential s
carious, due to danger of being wrecked. CLIMATE determines
working season and hence the annual output and return on inv
dredge of a given capacity. The minimum gold content of w
is higher where the season is short than where operation is cont
climate increases costs, because the dredge must be heated and
protected from accumulations of ice. See Bib (408, 432, 409)
of successful winter work. TRANSPORT FACILITIES are more in
for other forms of placer mining. The weight of the machinery
for small dredges; attempts to sectionalize a plant for mule
have not been successful. The high first cost of a dredge whe
are lacking militates against the construction of large boats in
(385, 433). LABOR. A small crew can handle a large yardage
except a few roustabouts are skilled men. Cheap POWER is esse
YARDAGE of gravel must be sufficient to amortize the initial in
yield the desired profit. A choice often exists between use of
several, of different sizes, with corresponding alternatives in firs
return, and life of property (Sec 25, Art 14). Closer estimates o
possible on well-explored dredging ground than on any other fo
property. An attempt is usually made to adjust the rate of

rty, to the LIFE OF THE DREDGE. This is practically machinery is repaired or renewed as necessary. The ıtled after working out an area, and installed else- a new hull. Steel hulls resist digging strains longer s not yet known. Wooden hulls last about 10 years.

Cal, states: The life of wooden hulls seems to be affected built, those erected in summer outliving others. Forced l is required to prevent dry rot.

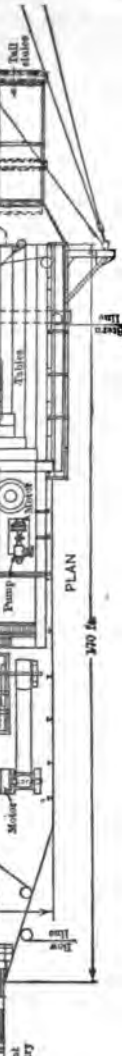

Fig 614. California Type of Gold Dredge, built by Bucyrus Co, Milwaukee, Wis (Plan)

Other forms sometimes used are the dipper, clam-shell bucket, and suction dredges; for data, see Bib (409, 435). In Australia, gravel pumps (Art 125), with or without a centrifugal pump for supplying giant water, are called pump-dredges. This work is not strictly dredging, though the pontoon carrying the pumps usually floats from place to place. For details, see Bib (436).

Construction and mechanical equipment. (For dimensions and weights, see Tables 111 *et seq.*) Fig 613, 614 show a recent California-type dredge.

Hull is of wood or steel, generally wood, the choice depending on size, difficulty of dredging and consequent strength required, relative first cost and life, and locality. Use of steel has been increasing, especially for large boats. R. G. Smith furnishes the following on Cal practice (Aug, 1917): Steel hulls have shown considerable pitting from action of the muddy water (439), and require repainting. Bitumastic enamel was used on the latest boats. A combination wood and steel hull is now being built for a new dredge; all loads are carried by steel, but the hull is of wood, reinforced on outside corners by steel plates; it is cheaper and apparently as good or better than the all-steel hull.

The bow end is divided, to form a well for the bucket chain and ladder. Depth of hull depends largely on the required displacement, the beam partly on the desired gold-saving area, the size of well on the dimensions of the digging ladder (which depend in turn on the depth of digging), and height of main gantry. Distance from well to stern is determined by length of screen and arrangement of machinery. Hull is designed to ride on an even keel when digging at aver depth, with a free board not less than 0.25 of its total depth (440).

Gantries (gauntries) (Fig 613). Front gantry carries the tackle for raising and lowering the dig-

STANFORD LIBRARIES

ging ladder. Main gantry supports the bucket drive and upper end of d
height depends on headroom required for the screen, gold-saving tables
Rear gantry carries the stacker and tackle for handling the spuds.

Bucket line is supported by the DIGGING LADDER, consisting of 2 hea
plate girders; lattice girders are used only for easy digging. In the
dredge, the bucket line is close-connected (Fig 613), a form able to excav
and dig a much greater yardage than the open-connected or bucket-a
tion, characteristic of the New Zealand dredge. The bucket line is c
on the ladder; for deep digging, an idler wheel reduces the sag of the line

character of gravel and size of dredge. Digging begins at the s bucket ladder raised; the dredge is swung across the face, the ladd 6 ft or more, and the dredge swung back, these operations being bedrock is reached, After bedrock has been scraped the dre ahead, by means of the 2 spuds and the bow lines, and begins an

Narrow deposits are worked to their full width in one operation; wide several successive cuts. In the latter case, the method depends on the n and is often modified by local conditions. A single dredge excavates a wide, extending through the property, then turns around and comes Tailing should be so stacked that it will not pile up on the sides of the rehandling when the adjacent ground is worked; this influences width of of cuts taken simultaneously in one direction (390, 438).

Clean-ups are made as described in Art 124. Yardage dug is u monthly; for a method of measurement, see Bib (448).

Resoiling. The typical California dredge destroys the la tural purposes. Flume-type dredges also dissipate a loam cove posit coarse and fines together, leaving a fairly even surface at a nal level. The problem of re-soiling dredged areas cheaply has attention. R. G. Smith comments as follows on recent expe Folsom district, Cal; see also Bib (449):

First trial was made by equipping a dredge with 2 short stackers dump at points between the stern and ends of the tail sluices. The lower end of arranged to segregate large stones, and dump them through a chute ne second dredge was fitted up similarly, but with 2 additional stackers (4 in

large rocks (Fig procedure filled tailings, gave a f tribution, and di dumps. But, du action of the wate no fines were left the soil was all i dredge pond. T ing (Aug, 1917) a 60 ft deep, with device to dewate posit them with t eventually, it m conveyers to dep fines on top of th are also under wa dredge with a dump hopper, a carry the topsoil and deposit it on this is successfu fairly uniform dis material, with a small percentage swell, covered with the original soil leveled and prepared for agriculture. Also, it would improve the muddy which in this field is probably the greatest problem. The Debris Co allow this water in the river, and settling basins in the old tailings are The problems of disposing of muddy water and leaving present farming condition are the controlling factors in many available dredging fields.

Cost data. Operating costs vary widely with character and size of and size of dredges, and with locality; the latter determines the length o and cost of labor, supplies, power and transport. Cost of repairs an during the dredge's life, being small at first, then increasing to a fair and often decreasing toward the end of an operation when only essen made. Discrepancies are found in comparing operating costs of similar

ons, due to differences in accounting. Short time records are not reliable criteria; example, note the yearly variations in cost of the same dredge (Table 110). perating costs in the U S range from 3 to 10¢ per cu yd. Under very favorable con- ns, costs on individual dredges are slightly below 3¢; on many Cal dredges, between d 6¢. Bib (435) gives costs with 3 to 7.5-cu ft dredges in Cal, in 1910. A dredge in o, in 1914, handled 4 670 000 cu yd at a total cost of 2.77¢. At Breckenridge, Colo, dges of the Tonopah Placers Co handled 3 242 240 cu yd during 1915 at 6.1¢. mirs estimates that costs in Alaska usually vary from 20 to 30¢, although lower fig- are sometimes claimed. He reports other costs as follows (409). Pato dredge, mbia: 8-ft dredge for year ended Sept 30, 1915, handled 1 420 000 cu yd at 16¢, ding general expense which, in 1914, was 4.8¢. Gumaos dredge, Philippine Islands: dredge, from Oct 1, 1912, to Dec 21, 1914, handled 1 850 000 cu yd at about 12¢. iled costs of American dredging are given in tables below. A dredge crew consists winchman and an oiler per shift, with 1 or more roustabouts on day shift; 1 dredge er may look after several boats; blacksmiths, machinists, teamsters, and other labor, depend on locality and nearness to custom shops; 3 8-hr shifts are usual.

rthern California. Data from J. F. Newsom. Table 109 gives the operating d of a 5-cu ft dredge (wood hull), built in 1908 for $65 000. It worked out the prop- on which it was erected, and in 1915 was dismantled and re-erected on a new hull other place for $51 242. The data are fairly typical of a 1-dredge operation. The al property was 5 miles from a R R. Ground was 12 to 20 ft deep, rather hard contained much clay in places; bedrock, mostly sandstone, somewhat irregular and red considerable scraping to clean it up. Electric power cost 1¢ per kw-hr. Second erty is 15 miles from R R. Gravel is 7 to 15 ft deep, lies on a soft lava-ash bed- which is ideal for cleaning up, is very easily dug, free from clay and boulders, but is y in places. On account of lack of depth, considerable bedrock sometimes had to ug, and low water required damming and re-pumping to secure flotation. This is of the lower cost 1-dredge operations in Cal. Electric power costs 0.75¢ per kw-hr, $150 per month. Dredge data: 59 buckets, capacity, 5 cu ft; total weight of bucket, lb; weight of lip, 166 lb. Ladder, 60 ft long; dredge designed to dig 24 ft under er. Total hp, 290; digging motor, 75 hp. Table area of original dredge, 1 700 sq ft; ebuilt dredge, 1 270 sq ft. Wages, original dredge: winchman, $3.25, oilers, $2.75, ers, $2.50. Wages, rebuilt dredge: $3.50, $3, and $2.75 respectively.

127. Drift Mining

The term is applied to the exploitation of placers by underground

Field of use is in mining rich paystreaks of moderate thickness, cut methods are impossible or would yield a smaller net return. La must be broken by blasting; if numerous, they may increase cost which is prohibitive.

Examples of drift mining are found in the ancient buried channels in C buried beach placers at Nome, Alaska, and the deep leads of Australia (Art creek gravels, where frozen, are often drifted, especially by small operato California and Alaska mining, many placers were drifted for rich streak with small capital; later the same deposits were profitably hydraulicked (385). Drift mining costs more than open-cut work, hence requires rich yield a profit. Ordinary thickness of gravel mined is 5 to 8 ft; up to 10 or cases, and down to 3 or 4 ft, which is about minimum for economic work in

General plan. The methods of OPENING are the same as for o ground mining (Art 15–17), with emphasis on a mode of entry tha the workings and eliminate equipment and operating costs of h pumping. But tunnel or drift entries are limited to bench grave elevated deposits like the old California channels. Details of LATE OPMENT (Fig 618, 620) vary widely with local conditions. In genera haulageway is driven from the point of entry close to the long axis streak, and on or partly in bedrock; in California, this opening is entirely in bedrock and connected by chute-raises with the worki gravel above. Crosscuts are driven from the central drift to the channel, or limits of the paystreak; auxiliary drifts also are driv deposits. These openings have both a mining and exploratory fu latter often predominating in fixing the dimensions of the blocks MINING is done by a form of longwall-retreating (Art 108), called " advancing longwall has been used in a few cases. Ground is b picks where possible; by hand drilling and blasting where necessar gravel is thawed before it is excavated; attempts to use machine failed (455). The roof of working places is temporarily supported posts and head boards serve in firm, cemented, or frozen ground; forepoling may be necessary in loose gr rows are best for transport in small min low roof; otherwise tracks are laid alon ing faces and the gravel shoveled into ca are shifted bodily after the face has ad 8 ft. Equipment for haulage, hoisting, ing is the same as in metal mines of s and output.

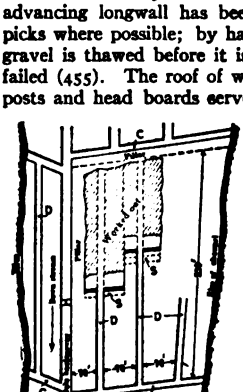

Fig 618. Layout of Drift Mine, Cal

Practice in California (ancient river c 116); data by R. L. Dunn and R. E. Brown, 1890 (456). Practice in the small number o now working does not differ materially from days. Fig 618 shows work in a wide part channel, Sierra Co, and illustrates the us Main haulageways *H* are 6 ft by 6 or 7 ft often requiring heavy drift-sets and close lag of these mines cover enormous areas, making nance of haulage openings a serious item. Cro auxiliary drifts *D* are 5 by 6 ft or 6 by 6 ft, ti lagged in soft ground, but not in as permanent a manner as the main haulage cuts *C* may be driven at an angle to the bedrock slope to secure the desired haula Breasting begins at the ends of drifts *D*, and retreats towards the crosscut from

of the working faces are indicated by dotted lines *S*. At ines, crosscuts *C* were 120 ft apart; in the latter, drifts ntain, development openings cut the gravel into blocks otect gangway *H*. In the Hidden Treasure mine, only sscuts *C* along the rim of the channel. These differ- s follows: At Red Point the gravel was hard and com- the breasts; but the distribution of gold was irregular, to define unprofitable areas. At Hidden Treasure the g ground, and all openings required timber; as the pay openings driven were those essential to mining. The d regular in value; the smaller blocks were doubtless eight breasted was only 4.5 ft. At Hidden Treasure, (120 eated were was with easts roof f ad- rking blast- easts er to

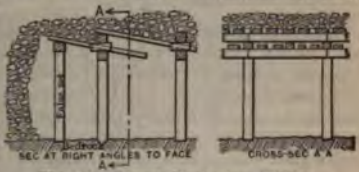

Fig 619. Breast Timbering, Hidden Treasure Mine

Fig 619 shows breast timbering at the Hidden Treas- oft gravel. In narrow paystreaks, California practice

ows a typical layout for paystreaks 75 to 100 ft wide. shaft or an adit; it usually requires timbering even in ts *C* are driven at intervals; in frozen ground they are carried the full width of the pay, retreating towards bered with sets in heavy ground, with posts and caps in mbered in solidly frozen ground. Purington describes bench placer 20 ft deep, on Anvil Cr, Nome: The pay-

streak, about 80 ft wide, consisting of 5 ft of gravel and 2 ft of bedrock, was opened by a central drift (6 by 6 ft) 600 ft long connecting with an adit. The drift was timbered with 3-piece sets 4 ft apart, of 6 by 6-in posts and 8 by 8 caps, lagged top and sides with 2 by 6 plank. Crosscuts were 40 ft apart. Breasts were timbered as in Fig 619; posts were 8 by 8 in by 7 ft, caps 10 by 10 in by 11 ft; posts were at he gravel was shoveled from plates into 21-cu ft cars. er exceeded 20 ft. The ground was so heavy that no ck was all recovered. Timbering cost 67¢ per cu yd ng 21 000 cu yd of gravel.

asts 50 to 100 ft long can be carried safely in winter; ked in small blocks. Timbering consists of 6 by 6 to cks and having short caps of 4 by 12 plank; posts are In winter, a space of 3 sets (9 to 12 ft) is usually kept round is ready to cave, the 2nd row of posts is lagged, Another slice is then taken off the breast. In sum- one time in this ground rarely exceeds 10 sq ft (390). of the Fairbanks district is like that at Nome; H. I. (458, 459). The gravel is nearly all frozen; shafts paystreaks over 50–60 ft wide, shafts are sunk near um aver tramming distance. The length of paystreak exceeds 400 ft (200 ft each way from shaft); greater transport to a point where it is cheaper to sink a new he length that can be worked downstream. Devel-

STANFORD LIBRARIES

opment and mining practice follow the general plan in Fig 620; if the wi
is 150 ft or more, an added longitudinal drift is usually driven on each si
drift. Little timber is used in breasting. Slabby roof is supported nea
row of stulls (Fig 621).

Fig 621. Timbering in Breast (after Ellis)

On Vault Cr, much of the ground is 200 f
streaks are narrow and irregular, but the gr
markably well. As it is important to follow
straight haulage drifts, driven ahead of stopi
ible. Fig 622 shows an advancing method
meet these conditions. A gangway is kept o
worked-out area by timbering with light 3-pie
lagging. Practice in other Alaska districts g
Fig 620.

Washing gravel. At mines opened by a drift or tunnel, th
are dumped at the portal into a bin feeding a sluice. Sluicing
tinuous; the bin is flushed out periodi-
cally with a small giant working under a
low head. A tunnel entry presupposes
rough topography and therefore natural
sluice-grades and dumproom. At mines
opened by shafts, the gravel is usually
hoisted to a sufficient height above the
surface to provide headroom for sluices
and tailings disposal. The gravel may
be dumped directly into a dump-box
(Fig 594) at the head of an elevated sluice, or into a bin arranged fo
sluicing. The latter plan is usual at small mines and where wate
costly. Bins usually hold a day's output; the upper boxes of the sluic
up after each run; frequent clean-ups are usually advisable at drift
of the relative richness of the gravel worked. In the far north, slui
sible in winter; the gravel is stacked on the surface and sluiced duri
summer. In California, tough cemented gravel is disintegrated in sta
with coarse screens, and then sluiced. Gravel containing much stick
passed through hexagonal trommels, or some puddling device, before e

with a hammer, and allowed to stand. Points he gravel thaws ahead of them; heavy blows are avoided, except where required by tight ground, as they may injure the point.

H. I. Ellis gives the following data at Fairbanks in 1915 (455). There are 3 types of bit. The diamond or square bit (*a*), Fig 623, is used in easy-driving ground, where stones can be pushed aside. The chisel bit (*b*) is for hard driving, requiring actual drilling; a cross-bit (like he chisel bit is hard to f 8, 10, 12, 16 and 20 ft ed). The 8-ft length is with short points, fol- breasts the points are d spaced There e driven ; steam e points allowed picked a face; wn and -in pipe the pipe the hole rocedure . Plan uch less hovelers thawing ers. In tely can together; but pointmen usually work in pairs, one point. Depending on the character of the gravel,

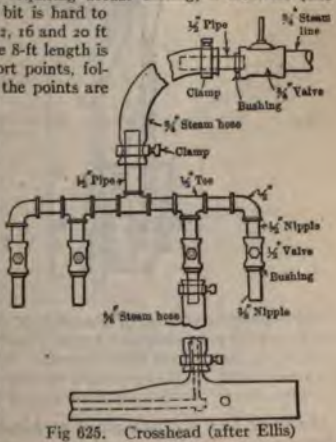

Fig 625. Crosshead (after Ellis)

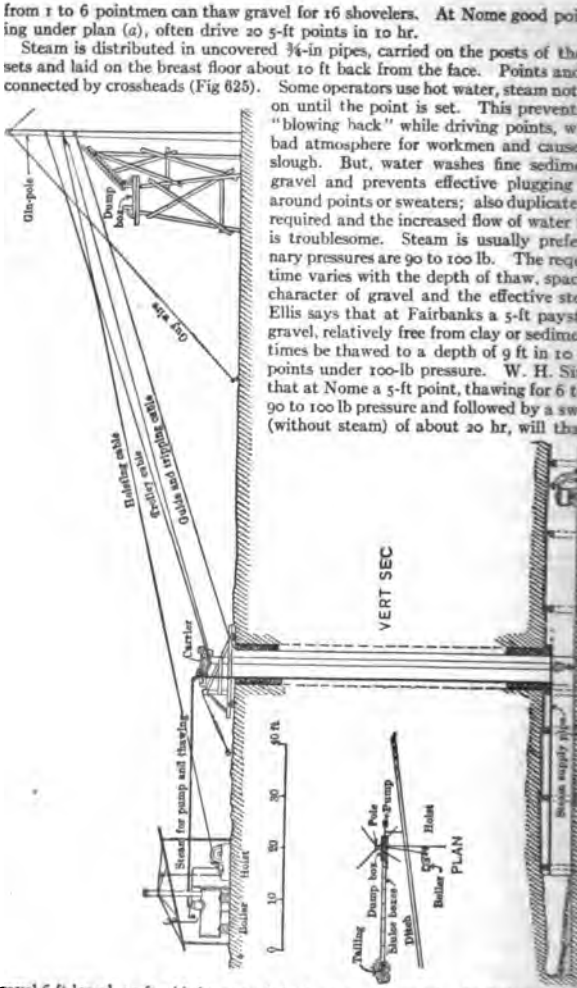
STANFORD LIBRARIES

from 1 to 6 pointmen can thaw gravel for 16 shovelers. At Nome good poi
ing under plan (*a*), often drive 20 5-ft points in 10 hr.

Steam is distributed in uncovered ¾-in pipes, carried on the posts of th
sets and laid on the breast floor about 10 ft back from the face. Points an
connected by crossheads (Fig 625). Some operators use hot water, steam not
on until the point is set. This prevent
"blowing back" while driving points, w
bad atmosphere for workmen and cause
slough. But, water washes fine sedim
gravel and prevents effective plugging
around points or sweaters; also duplicate
required and the increased flow of water
is troublesome. Steam is usually prefe
nary pressures are 90 to 100 lb. The req
time varies with the depth of thaw, spac
character of gravel and the effective st
Ellis says that at Fairbanks a 5-ft payst
gravel, relatively free from clay or sedim
times be thawed to a depth of 9 ft in 10
points under 100-lb pressure. W. H. Si
that at Nome a 5-ft point, thawing for 6 t
90 to 100 lb pressure and followed by a sw
(without steam) of about 20 hr, will tha



gravel 6 ft long by 3 ft wide by 3 to 4 ft high, or 2 to 2.5 cu yd. In drifting in t
the duty of 6-ft points averages 3.75 cu yd per 10 hr (408). BOILER CAPACITY
varies locally, but is about 1 b hp per point. When drift mining on the Third Be
was at its height, the b hp per point was from 1 to 2, aver 1.5; attention to d
duced this figure. For further detail, see cost data below and Bib (390, 408, 45

Hoisting and surface plant at Alaskan drift mines differs fro

centralized system, which reduces the num-

STANFORD LIBRARIES

length or size of sub-levels, crosscuts, laterals, shaft stations and trackage wise required. Such saving must be balanced against cost of installin maintaining the proposed haulage system.

General formulas. Let D = useful duty per shift, mineral-ton-miles; G = gro per shift, ton-miles; d = distance mineral is to be moved; ft; s = aver speed moving, ft per min; t = time loading and discharging per trip, min; T = mineral per trip, tons; T' = tare per trip, tons; C = time of 1 complete cycle, min; m = working time per shift, min.

$$D = \frac{m}{\frac{2d}{s} + t} \times \frac{dT}{5\,280} = \frac{mdT}{5\,280\,C}, \quad \text{and} \quad G = D + \frac{m\,2\,dT'}{5\,280\,C} = \frac{md\,(T + 2\,T')}{5\,280\,C}$$

Useful duty D varies directly with distance, speed and wt of mineral per trip, versely as the time required at terminals. If the gross duty limit has been reac useful duty will vary inversely as $(T' \times 2)$. These principles apply to all kinds o port, from shoveling to locomotive haulage. Despite the rule that cost per t other things being equal, varies inversely as the unit load, underground conditions require small-scale equipment. But many large-tonnage installations exist, e in coal, iron and copper mines, and methods now vary from the most primitive to of standard R R equipment.

2. Primitive Transport Methods

Packing. Mineral is carried in sacks, skins or baskets on backs or heads of m women, in primitive countries, or occasionally in narrow, tortuous workings, or i gency work. Unit load is usually 60 to 150 lb, but, in Latin America and the peones and coolies can carry more. Duty varies widely, but approximates 12 to hr per ton-mile. Boxes or hand-barrows, holding 200 to 700 lb, and carried by 2 men, are slightly more economic, but if there is room for such practice better met usually feasible.

Shoveling. Transport by carrying or casting with shovels is prop as a last resort. One man can move 1 ton 100 ft in about 2.5 hr, equiv 125 to 160 man-hr per ton-mile. (MUCKING is a common term for under shoveling in stopes or development work.)

In stopes, with chutes 30 ft apart, the standard duty in many mines is 20 cars (tons) per shift, including sledging or blockholing lumps, and stowing filling. chutes are advantageously placed with reference to the mineral faces, shovelers h to assist miners, but if they have also much sorting to do, their output may b reduced. (For mucking in connection with tramming, see Art 9.)

Wheelbarrow transport, exclusive of loading, costs at least 1 man- ton-mile, and is justified only in temporary work, or where first cost of tr equipment is not warranted. Short exploratory workings and small, l stopes, where the only alternative is shoveling, are the only proper field barrow in mining work.

Best mining barrow has 3 cu ft capacity, No 14 to 16 B & S gage pressed s handles, frame, and wheel-guard of steel pipe; max height 21 in, wt 70 to 80 $35 to $45 per doz, fob factory. For surface work in very hot or cold climat handles are preferable. For thin seams a flat barrow without legs is used.

3. Mine Cars (1, 2, 3)

Standard design. The importance of the underground car justifi care in design or selection. If possible, a single design suited to local co should be adopted. This cannot be done where hand-trammed, s or sub-level cars and larger mechanically hauled main level or adit all used, and in large mines several designs and sizes are employed. compromise design is feasible, standardization is advantageous in sim repairs and the stock of repair parts.

el or composite construction. Wooden cars are bulky, are less durable, but are more easily repaired than steel. ing, and in collieries the number of composite and steel osite cars usually have wood stringers for the truck, and r is hinged on its truck for dumping in one direction, or ection to truck to dump in any direction. When con- e centered over the wheel-base, to equalize wheel loads ping.

rs are simpler and usually lower than others of ease of loading because of the low sides, simplicity, pacity to wt. Disadvantage: they can be dumped

4. Mine Car Details (2)

Draw-bar, coupling, and bumper. When cars are to run in t frame or body must transmit and withstand both tractive and impac For light cars, separate draw-bars should be protected by bumpers, a signed for 10 times the nominal locomotive draw-bar pull, to allow braking and abuse.

Small metal-mine cars are sometimes coupled by chains and rings at the ver of body (Fig 11). This requires 2 connections, but on curves the outer chains tension, curve friction is supposedly reduced, and couplings are more accessi of 2-ton capacity or over should have combined spring couplings and heavy C- (Fig 9, 13). 1 spring and 1 rigid coupling make a good combination for light cars. should be rounded to avoid interlocking on curves.

Car wheels. MATERIALS: C I, cast, pressed or manganese steel. Sta wheels are of definite composition, annealed to give toughness, and with dee flange and tread. The treads are too hard to be trued on a lathe. Hubs are worn, but readily machined and bushed. When scrapped they are salable to l ries. Cast-steel wheels are at least 30% lighter than C I; are tougher, not breal impact (as iron wheels may), wear more rapidly on the tread, but are easily In remote regions they are worth less per lb as scrap. Wheels of pressed-steel tougher and lighter than cast steel, easily machined, but cannot be made in one self-oiling recesses. Some mines give satisfactory reports of them. Manga wheels are hard and tough, and outwear any others of the same design. They cannot be machined with tool steel, and in many mining districts make unsala DESIGN. Diam, 8 to 20 in; tread, 2.5 to 3.75 in, coned $\frac{1}{16}$ to $\frac{3}{16}$ in (M C B coning is 1 in 20). When treads become grooved, wheels should be trued on discarded; grooving causes derailment on frogs and increases tractive resistance, on curves. Flanges are from $\frac{7}{8}$ to $1\frac{5}{8}$ in deep. M C B standard gage is m $\frac{5}{8}$ in above base of flanges, and is $1\frac{3}{16}$ in less than the straight track gage.

Wheel bearings. LOOSE WHEELS are held on the axle by cottars or linch-pins by bolts or key blocks engaging annular grooves in axle (Fig 18), or have outside boxes and inner axle collars (Fig 4). With finished collars, hubs should be co to fit. Hub bore may be machined, or left rough for babbitting, or reamed out steel, brass or bronze bushing (Fig 19). ROLLER-BEARING WHEELS (3) are he reduce tractive resistance, and are now widely used on colliery cars. They re inspection and lubrication. SELF-OILING WHEELS have hub caps, thus maki reservoir (Fig 11), or are cast with reservoirs in the hub, spokes (or wheel disks), feed holes to the journal, and a screw or spring-plugged supply hole (Fig 10, 18). many designs on the market. TIGHT WHEELS may be keyed, or bolted through cro in the axle; but a close fit is better, the wheel being forced on the axle by a hydra

Axles may be fixed or rolling. Simplest and cheapest is a square axle bolte frame or car bottom, with outside loose wheels (Fig 10). As there is no protec dust or oil leakage, the hub bore wears rapidly, increasing friction and liability ment. A hub cap keeps out most dust and saves oil; bushing takes up wear an friction. Roller-bearing wheels, with long bearings, are excellent on fixed axles, are often used in pairs on rolling axles, which is not a logical design; rolling a

tation positive. Axle boxes often have no caps, and even . Open pedestal boxes with axle held by a U-bolt are heap, but the axle wears rapidly. e better. Many dust-proof bear- from simple shrouds, multiple felt e continuous sleeve enclosing the es, as the Anaconda (Fig 9) or

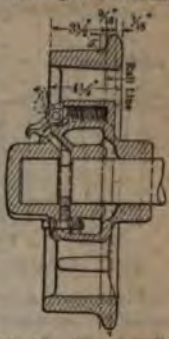

Fig 18. Faught Self-oiling Wheel

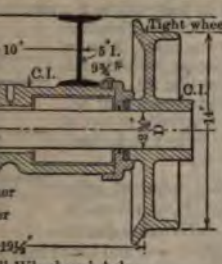
standard R R practice, the tread the increased length of the outer flanges crowding against the rail, smaller diam. With the short- eads cannot be sufficiently coned hus, on 24-in gage, a 20-ft radius wheel to travel 3 ft or 10.5% far- ed wheels must therefore either is avoided by loose wheels. Or,), both wheels are tight, but are inuous sleeve journal. Each axle or saddle key, riding in a slot cut the design is the 2-piece axle and ts. McCaskell truck (Fig 19) has r shroud between bearings, and a solid axle, with 1 tight heel gives differential travel on curves, so that hub wear is negligible, or is provided for by bushing. Cased roller bearings for the axle (3), and a self-oiling loose wheel, would give an ideal combination to minimize tractive resistance.



ll Wheel and Axle

Lubrication of wheels (1). Thorough lubrication is essential for low tractive resistance. An oil bath on a standard R R axle reduces friction to 10 to 15% of one side of the journal. Open, unprotected pedestal every trip, and, when used, there should be oil reser- with revolving brushes or cams to oil or grease axles ver.

S as for drill-steel, timber, wate men, can advantageously be m mine shops during dull period nal labor cost; but, for star even the best appointed mine rarely compete with mine car makers, either in cost or quality of product rates on manufactured cars are usually higher than on lumber or down car parts.

5. Mine Track (4, 6)

Wooden rails, 2 by 3 in or larger, are often used in metal mines, for small-s porary work, and in collieries for branch track in rooms or breasts. Friction to sliding of braked wheels on heavy grades is greater on wooden rails and le to wheels. In its simplest form, the rail is spiked to the ties by 4-in or larger wire nails. A better form, for convenience in relaying, holds the rail by wedges in daps in the ties (Fig 22). Facing wooden rails with strap iron increases their life, but reduces sliding friction practically to that of the T-rail. Straps are ⅜ or ½ by 2 in, fastened by countersunk spikes or screws.

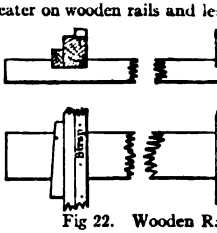

Fig 22. Wooden R

Steel rails are made in 3 standard series of sections, the Amer Soc C E, and A and B series of Amer Ry Assoc; also in many special shapes. For mine track thick web and broad base are best, because of t ties, and frequency of corrosive water. Amer Soc C E sections most n

ENGTH: Fig 24 shows minimum wt of rail and max
ed for 1½ and 3-ft tie spacings, to give reasonably
an indicated for given loads will reduce track resist-
ance and maintenance costs, while lighter rails should be used only for temporary work. For locomotives, rails lighter than 25 lb will not keep alinement, and should not be used on main lines. FOR CONDUCTIVITY: rails for heavy traffic are usually amply large for return circuit for electric haulage, but with light equipment the size of rail for economic conductivity, rather than the wheel loads, may be the limiting factor in determining wt of rail (Sec 42, Table 3).

½ and 3-ft Tie Spacing

Bonding. The contact resist-
o great as to be equivalent to an open circuit. The best of
lice bars, and rails should be cross-bonded at about every
eing connected to the negative pole to minimize corrosion.

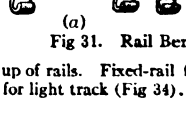
Switches (7). Standard point and stub switches and many other used in mines to transfer cars from one track to another. The point or (Fig 32) consists of 2 "points" or latches, lead, and follower turnout rails, and frog with guard rails opposite frog. On blunt switches the toes of the frog and heels of the point rails meet, otherwise filler rail lengths are inserted. Facing a switch, it is passed from the point end; trailing, from the frog end.



(a)
Fig 31. Rail Ben

Frogs. The rail crossing may be a single casting (Fig 33), preferably of manganese steel, or be built up of rails. Fixed-rail filled and bolted, for heavy track, or riveted on plate for light track (Fig 34).

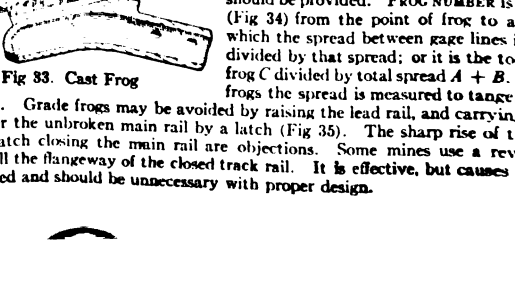


Fig 32. Point or Split Switch

frogs have one wing rail movable, but held by a spring against the frog p wheels on the main track pass over no gap. Standard frogs have straight r narrow-gage blunt turnouts, curved f ter, though they are not interchangea and left-hand turnouts, and a turnou should be provided. FROG NUMBER is (Fig 34) from the point of frog to a which the spread between gage lines divided by that spread; or it is the to frog C divided by total spread $A + B$.

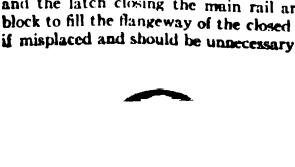

Fig 33. Cast Frog

frogs the spread is measured to tange frog point. Grade frogs may be avoided by raising the lead rail, and carrying flange over the unbroken main rail by a latch (Fig 35). The sharp rise of t and the latch closing the main rail are objections. Some mines use a rev block to fill the flangeway of the closed track rail. It is effective, but causes if misplaced and should be unnecessary with proper design.

ts are frequently included in tramming charges, thods, they should be kept separate. For LOAD- ng to a shaft station, under best conditions, the gh the shift will be not less than 4 min per round 800-lb load 1 man can tram 32 cars 1 000 ft, or 90

STANFORD LIBRARIES

cars 100 ft in 7.5 hr actual work, and his output will be 5.5 and miles respectively. With chutes stopped by bridging or jammed blocked by spill, derailment, ore shortage, or repair work, the o reduced to the vanishing point. LOADING BY SHOVELING. When mittently, good shovelers working under contract will handle up hr from steel plates into low, open-end cars, or 2 tons from a rc buckets or revolving dump cars. Aver performance when trammir ft is from 10 to 20 tons per shift. AVER DAILY DUTY of contract s Missouri lead districts is (H. A. Guess) 18 tons, while Higgins esti Mucking costs for all kinds of work usually run much higher on d or with irregular supply of ore or cars. On basis of loading at rat hr, the duty of a man with the 1 800-lb car load would be: loading 19 cars 100 ft = 0.32 ore-ton-miles, or 14 cars 1 000 ft = 2.39 ore shift. If trammers or shovelers have to help miners place timber or shoveling plates, their tramming output will be proportionatel

Examples. In MICHIGAN COPPER MINES tramming is usually done on t mum-wage and bonus systems, and includes loading by shoveling and hanc floor or footwall into large, low, open-end cars, and tramming by 2 men According to J. MacNaughton (1913), the distance trammed at 11 proper 171 to 900 ft, averaging 609 ft. Output per man-shift was 12.12 to 19.48 14.76, and the ore-ton-miles per man-shift, including loading, was 0.47 t aver. In loading from chutes into the cars shown in Fig 4 (Art 3), the tramming 600 ft is 6 to 9 ore-ton-miles (F. W. Denton); when shovel-lc 10 cars or 3 ton-miles. The standard in many BUTTE MINES is 15 cars shovel-loaded and trammed not over 100 ft in drifting work, and appr loading from chutes. Cars aver 1 600 to 1 700 lb rock, or 1 700 to 2 000 lb CONSOL MINE, Ariz, on tramming drifts, the aver duty for a distance of 25 to 1-ton cars per man-shift, with bonus of 3 to 4¢ per car over 50 cars. On same mine, a gang of men loaded from chutes 150 tons per man into 5-ton ca A I M E, Bull 102). In PORTLAND MINE, Cripple Creek, Col, trammin and waste from Lee stope 330 to 530 ft to shaft or waste chute cost 15.4¢ p per ton-mile; duty was about 2.2 ton-miles per trammer shift. In the 35 365 tons ore and waste were trammed an aver of 975 ft, at cost of 1: 98¢ per ton-mile, or 3.2 ton-miles per shift. In MT ROYAL TUNNEL, Ont, back and 4 loading cars ordinarily loaded 7 cu yd per man-shift; in a rec loading muckers averaged over 12 cu yd (max 15 cu yd), nearly 2 hr bein blasting (*Trans* Can Min Inst, Vol 17, p 182) (8).

10. Animal Haulage (10, 11, 12, 13)

Duty. Mules and horses at underground work travel 3 to 15 With enough cars, and grades not over 2% against the empties, t age 7 to 12 miles on main haulage lines, and usually below 9 mile work. Many records show duties from 50 to 100 gross ton-mile and empty haul) per animal, or 25 to 66 mineral-ton-miles per sh

To justify animal haulage as against tramming, a minimum of about miles should be done on a given level or entry per shift, unless there are The economy of animal haulage increases with tonnage. Using tandem, and longer trains, increases effic of both animals and drivers, though more sidings are required. For duties below 200 mineral-ton-miles per day on 1.25%, it has been claimed that no mechanical system can compete i animal haulage using a string team of four. The exact dividing line dep conditions, and costs of labor, power, and feed.

Cost of animals. Good mules cost $150 to $300, depending c general condition. Their underground working life in the U S is

Horses *vs* mules. Mules average smaller, require less headro heat and neglect better, and are less liable to foot lameness than hor will eat roughages which horses refuse, but are less apt to overeat, and subject to colic or founder. Horses are heavier, better built draft an mules, average more reliable, haul larger loads, and require little or no per 100 lb live wt than mules on similar work. They are more sp mules, and a nervous horse is apt to rear and injure his head ag Mules are more generally used underground than horses, but, whe ways are large enough and the duty sufficient for heavy horses, the of mules are debatable, and where there is headroom many coal ope use large horses in preference to mules.

Examples. According to the Illinois State Co-operative Reports for 19 mules costing $175 to $275, used for gathering colliery cars for locomotive worked at high speed, and the underground working life has been reduced to mules then selling at about $40. Cost of feed, shoeing and harness repair is 7 day. In the best managed mines, cost of feeding mules with corn @ 60¢ pe hay @ $15 per ton averages $10 per month, some exceeding $14 per month. 1 300-lb mules haul 75 loaded trips 700 ft on 2% grade in favor of the load. consists of 4 1 000-lb cars, with 3 500 lb coal each, or 18 000 lb gross. Gros mileage per mule is 54.67, or 34.80 coal-ton-miles, equivalent to about 10¢ p mile. At another mine, 1 mule on gathering work on 0.5% favorable grades, of 3 cars 1 000 ft, with a duty of 24.43 coal-ton-miles, total cost being 17.6¢ p mile. At another mine, with 2% favorable grade, a 3-mule spike-team hand 17 1 800-lb cars, each holding 2 100 lb coal, or 22 100 lb gross per mule, co to a tractive effort on the return trip of at least 300 lb per mule.

In Alabama-Tennessee mines (1904, C. E. Bowen) aver for 500 mules in 6 and care, 34.9¢ per mule; int on cost, 3.3¢; deprec, 7.0¢; total, 45.2¢ per d 276 days = 59.8¢ per working day. Shoeing and harness 3 to 6¢ (aver 4.3¢) $1.762 per working day. Aver duty 3.9 to 33.2 net ton-miles per mule, as fo

driving wheels slip, its max drawbar pull is limited by the adhesion wheels to the rails. COEFF OF ADHESION is the tractive force requi drivers ÷ wt on drivers. Table 8 gives approx values for mine lo Makers' tables are usually based on 20 and 25% adhesion, and 20 to 4 resistance for train on the level.

General formulas applicable to all types of adhesion locomotives: Let adhesion; C = force required to move complete train, including locomotiv drawbar pull, lb; E = fric resistance of locomotive, lb; F = fric resistance per ton; G = grade resistance, lb per ton; H = dynamometer or drawbar motive; L = wt of locomotive on drivers, tons; S = speed, miles per hr; T of train, tons. Then:

$D = T(F \pm G)$ ..... (1) $C = D + E \pm (L \times G)$ .....

$L = D \div (2\,000\,A - G)$ ..... (2) $H = D \times S \div 375$ .....

Total dynamometer hp-hr for M miles, @ aver drawbar pull D, $= DM \div 3$

From (1) and (2), $T = L(2\,000A - G) \div (F + G)$ .....

Effect of grade on locomotive capacity. Assuming a max tracti the level of 25% of wt on drivers in Eq (6), then locomotives can move on drivers the gross train tons given in Table 9. Multiply these weights on drivers for the locomotive under consideration, and for satisfacto deduct approx 25% from the total to allow for acceleration and cor

For greatest effic in power haulage, the grade should be that of equal tract The rapid loss in effic with increasing grades makes the economic grade lir motives usually below 3%. There is also liability of runaway accidents on ste

Rack-rail locomotives have much better effic on grades than others, becau bar pull with ordinary drivers can not exceed the adhesion, and while the pow a locomotive, $D \times S$, is not constant for varying speeds, the rack-rail type, l to the track, can, by decreasing S, increase D above the adhesion limit, or for a of D can decrease locomotive wt below the adhesion requirement. Rack rail geous on long moderate grades, or in rolling seams; it is the only practical ty over about 6%, and can be safely but not economically used up to 15 o Schneider, *Trans* A S Mech Eng, Vol 14, 1893.)

12. Steam Locomotives (14)

Steam locomotives are usually impossible underground because of their e and vapor, but may be used in adit mines having large entries and abundant Oil burners are preferred to coal burners, because of better control of combust retical MAX TRACTIVE FORCE of a steam locomotive is $C = (d^2 \times l \times p \times B) \div$ where, d = diam cyls, in; l = stroke, in; B = boiler press, lb; W = diam dri in; p = 0.85 for simple, 0.6 for cross-compound, or 1.2 for Mallet compou d being for high-press cyls. Substitute for C its value from Eq (3) in E termine sizes of cyls and drivers. MACHINE FRICTION E = loss between cyl bar; it increases with the ihp, but its ratio decreases with increasing load. consolidation locomotive show E = 10% of ihp with heavy load and 22% wit 82, Ill Exp Sta).

umption of simple R R locomotives aver approx 4.5 uel oil and 27 to 32 lb water per hp-hr. Superheaters very 4 10° superheat. Compounding saves 10 to 20% ood condition, but advantage may be more than bal- he overall consumption of locomotives, including stops approx 50 to 100% more than above figures.

eports of Pa (1912) showed 45 steam locomotives under- bituminous mines. Many were oil burning and some were oil.

6-wheel switch locomotives, with 62 tons on drivers, were wing are aver results for 3 yr: round trip, 4.5 miles; grade 4 16-cu yd 49 000-lb cars = 90 tons material per trip; 18 12 563 gross or 3 645 net ton-miles. Daily cost of operation er, 48 tons; oil, 5.32 pints; grease, 4 oz; waste, 1 lb; wages man), $9.95 per shift; locomotive maintenance, $50 to $70 for tires, boiler, machinery, and painting.

Gasolene Locomotives (15, 16)

have the flexibility of steam locomotives in radius of k are geared for speeds of 3 to 12 miles per hr. They no fuel when idle, and are less dangerous than steam The exhaust gases and cost of gasolene are the limiting other types.

od (16), the max volume of CO produced when feeding gaso- s 5.75% of the piston displacement, and, under the worst % of the exhaust gases are CO as against 4 to 6% normally. 000 volumes air for continued breathing and should never re concludes that gasolene locomotives require from 7 840 ; by 5-in motors, to 35 140 cu ft per min for 6-cyl, 8 by 7-in % dilution. Stopping in dead air, or traveling with the air y be dangerous. The exhaust should be washed and cooled deodorizer before discharging, which does not, however, se of motor should be limited by the available air current. gainst leakage at the carburetor and when charging tanks.

icensed Automobile Manfrs for gasolene motors is: e d = diam cyl, in; n = number of cyls, with piston per min. This formula is conservative for automobile ouretor unfortunately used in many mine locomotives than good automobile motors. The uncertainty of

17. Rope Haulage (22, 23, 24)

Systems: (*a*) self-acting or gravity plane; (*b*) engine plane; (*c*) ta
endless-rope. Of these, (*b*) and (*c*) are commonest. CONDITIONS for
age: large tonnage, and grades which make locomotive haulage ineffici
Table 9). Straight haulways and uniform grades are desirable but no

Ropes, sheaves, and rollers. ROPES on flat grades, or wherever especia
to abrasion, as in dragging on the ground or over track ties, should have
strands. The small-gage wires of standard 19-wire hoisting rope wear too
Art 14). A short length of chain at the coupling protects rope from dam
bending, if the cars overrun. Horiz SHEAVES or vert ROLLERS on curves shoul
alined, and of large diam, to reduce bending stresses; 1 large sheave is better
small ones. Where rope crosses the rail on curves, guide strips should be
minimize friction (Fig 56, *b*). Track rollers aver 5 in diam by 12 to 18 in lo
to 25 ft on straight track; closer on curves. At points of special wear, C-I ro
(often made of a pair of car wheels, bolted together with flanges outside).

Self-acting or gravity plane. Descending loaded cars raise t
It is often used on the surface, is effective in slopes or long rooms on
flat for mineral to run in chutes by gravity, and in general serves to t
to a lower level, on main haulage lines, or from a blind level to main

Angle of flattest self-acting slope. $Sin\,\alpha =$ (total friction F, lb) ÷ (wt of
of unbalanced portion of rope R, lb), in which $F = [$(wt loaded and empty c
on both tracks, lb) $\times \cos\alpha + f'$ (wt rollers + drums, lb)$] \times f$; where $f' = 0.1$
coeff rolling friction = 0.012 to 0.025. Friction is often figured on basis of
only, in which case f should be larger. This equation shows that profile of pl
concave, and that heaviest trip, highest ratio of useful load, shortest distanc

rkable slope. Using a tail-rope cancels unbalanced R, teepened at top, or "knuckle," so that the grade exceeds rting trip promptly. Acceleration $a = [(P_d - P_a) +$ = accel, ft per sec per sec; P_d = descending pull, lb = ing pull, lb = $(T_t + R)$ $(\sin\alpha - f\cos\alpha)$; T_l and T_t = = slope angle. If slope changes, take value for α at top for R. Length of slope l (ft) required to attain veloc v nsion R_t in rope will occur when starting or stopping with $(\sin\alpha - f\cos\alpha)$. Number of cars required per trip to

$$\left| + \left[\left(\frac{\sin\alpha}{f} - \cos\alpha \right) W_1 - \left(\frac{\sin\alpha}{f} + \cos\alpha \right) W_2 \right].$$

ope, lb; W_1 and W_2 = wt of 1 loaded and 1 empty car friction.

54, a to i). It is best to avoid switches on planes by n (d) a simple automatic switch is used at L, as shown in

ps and Lashing for Endless-rope System

STANFORD LIBRARIES

Cars are attached to rope singly, or in trains, by grips. A single-track syste its travel for loaded and empty cars; double-track system is continuou attached without stopping rope. Aver speed, 4 to 5 miles per hr; max, rope may be over or under the cars. Some foreign collieries support overh cars, requiring steady supply and regular spacing of cars and slow speed (per hr). With under-rope, at switches the rope must pass below ties, by cast rollers. Cars are attached to rope by lashings, or more commonly by (*a*) lever which grips rope either by the eccentric pull of car, on continuou clamping for undulating grades; (*b*) wedge grip (sometimes combined wit dulating grades; (*c*) screw grip, the better designs being good for variab Fig 58 shows various grips and lashing. Double lashing is required on unc Branch lines can be run by a bevel-gear drive, from a fleet sheave on mair rate endless rope on branch, but branches are more difficult to install and tail-rope system. Endless-rope system requires ⅓ less rope than tail-r cheaper, and can take or leave cars at several sidings more easily, but ten increases maintenance, especially on curves. With double track, both ru be between rails, on uncovered rollers so that grips may pass.

Max tension in rope, in lb: $D = f \times \left[\frac{Ml}{v}\left(1 + \frac{2W_2}{W_1 - W_2}\right) \times 2rl\right]$, wh fric; M = mineral output per min, lb; l = length of haul, ft; W_1 and W_2 and empty car, lb; r = wt of rope per ft, lb.

Endless chain is used in U S for short car hauls, and occasionally ab ground systems. Chains are 5 times heavier and cost more than rope o and break without warning; but they have 2 to 4 times the life of rope, are because of wt are good for over-chain haulage on synclines, and cars are by forks. Under-chain is used on short inclines with clips or grip carriage (See catalogues of Jeffrey Mfg Co, Robins Conveying Belt Co, and Link-

Rope-haulage costs are usually combined with gathering cost power charge is estimated, data are only approx. At Sherrard collier when hauling 700 to 800 tons per day, aver haul 4 000 ft, max 2.25 including maintenance of track, wear of ropes and sheaves for rope mule haulage, was 14¢ per ton; rope speed, 10 to 16 miles per hr.

18. Miscellaneous Haulage Methods

Gravity roads must have sufficient grade in favor of loaded car in motion, the empties being returned by hand, animal haulage,

Grade at the top or "knuckle" must be greater than angle of inertia (must have a starting push; aver slope must exceed the angle of rolling fr required vary with quality and condition of rolling stock and track; for s slope is short, max grade should be less than the probable minimum angle o In rooms or slopes on flat rising pitch, cars can be delivered to loading po animal, or locomotive, and returned to the drift or entry by gravity. On ropes should be used.

Telphers or monorails with buckets are used occasionally where tr impracticable. SHAKING or BUMPING CHUTES are used in flat stopes on U S coal seams, for short local transport (Sec 10, Art 92). Skips o sometimes replaced by conveyers for slopes under 25° (25, 26, 27).

is seldom practicable entirely to eliminate hand development and exploitation should be planned or. In METAL MINES, tramming is usually the only ore, waste, and timber in flat-back or slice stopes, ary workings (Sec 10).

ould be so placed that all material will reach its destina- ween working places and main-haulage system. Thus, at g averages about 300 ft for ore and 500 ft for rock from en mine, less than 200 ft; at Miami, Ray, and other new 25 to 100 ft for normal stopes; on the Mesabi iron range work and seldom over 150 ft in irregular bodies (see s, the miners' contract commonly includes tramming or breast road. Mules or gathering locomotives then p siding on the main haulage and return the empties. ssed air locomotive often hauls to the working face; but, nals, the necessary delays and small tonnages handled in nalysis of cost of gathering and returning cars, to prove tive service is profitable (E. Brackett, *E & M J*, Vol 74, pe haulage systems are more definitely determined by the workings, than when the more flexible prime movers are frequent examples are found of alternating animal and sual cases where locomotives with their trains are taken

WINDLASS AND WHIM

1. Hand Windlass

Windlass has low efficiency and small capacity; hence, limited to sinking winzes, beginning shafts, and small-scale development prospecting, economical limit of depth is, say, 75 to 100 ft.

Principal dimensions for ordinary windlass (Fig 1): Diam of barrel, 6 t to suit size of shaft; crank arm, 14 to 16 in; length of handles, 15 to 18 in; of barrel above platform

Fig 1. Hand Windlass

$12 to $18 complete, with cost of labor than

Capacity and cost An average man can of work per min, app 20 lb at crank. Hence ity is 125 ft per min 15-in crank, gives 16 r ing speed of 33.5 ft per barrel. At 75 lb gross load per man (125 × 20 ÷ 33.5 = 75, nearly), allo time for filling, dumping, and lowering bucket, 2 men can hoist 7 200 lb from Fig 2 shows cost and capacity, for different depths, with 2 men and 1 buck per hr, 3 min being allowed for filling, dumping, and lowering.

Manila rope, 0.75 to 1 in diam is best for windlass; wire rope tends to kink and is not suited to small diam of barrel.

Buckets may be of heavy sheet iron, or made from half of an oil barrel, with iron bands top and bottom. Bail, 0.75-in round iron, with eye at center; ears for bail are the ends of a 0.25 by 1.25-in strap, passing down each side and under bottom of bucket, with 3 or 4 rivets on a side. Wt of bucket, 60 to 75 lb (Art 21).

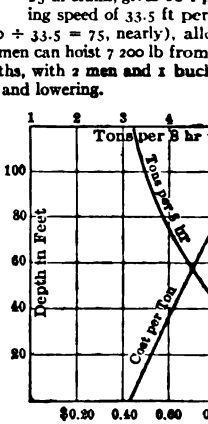

Fig 2. Hoisting with

2. Horse Whim

Uses. For sinking when depth and capacity required are too great for a windlass; for preliminary or small-scale development work, not warranting a power hoist; or for beginning a shaft while installing steam or electric hoist.

Construction. When made at the mine, whim is entirely of wood exc small quantity of bar iron (Fig 3) (1). This design is called "malacate American countries. Axis of drum is vertical, and arm or sweep is attac

under the conditions) could load in time required for each hoist. (**Note.** — Ma rating of whims is sometimes equivalent to 2 or 3 times the average work of a

Rope for whims is sometimes hemp, but is better cast steel, of ordinar ⅝ in diam. (For wire rope data, see Art 14.)

Buckets should be light; ⅛-in plate is thick enough, if reinforced at shallow bucket is better than a deep one, as it is easier to fill and dump. Dia at top, to prevent large stones from wedging fast when dumping; but for in where bucket slides on skids, a barrel-shaped bucket is necessary. Bucke attached at top are safest, but those swinging on trunnions on the sides, bel gravity, are easier to dump. Proper capacity for 1 horse, 8 to 9 cu ft. An 8- of ⅛-in plate, weighs 130 to 150 lb and costs 8 to 10¢ per lb.

HOISTING ENGINES

3. Geared Steam-driven Hoists

Small geared hoists, for prospecting, development, or mines of put and depth, are self-contained, with inexpensive foundation, an design. For smooth running, gears are cast from machine-cut patt cut from the solid are better, but cost more. Ratio of gearing, from 1 at least 2 teeth of pinion are always in contact with those of spur g cone and band friction gear, see Art 5.) Drums should be at least 20 in less the diam, the shorter the life of rope. Lowering is usually don but reversing gear may be had at about 10% added cost, and lowering u is safer. Cost of first-class geared hoists averages about 10¢ per lb (

Table 1. Lidgerwood Portable Hoists, Single Cone-friction D

Rated h p	Cylinders		Drum		Average hoisting load, lb	Average hoisting speed, ft per min	Bed-plate	
	Diam, in	Stroke, in	Diam, in	Length, in			Width, in	Leng in

35	9	10	41	40	3 500	350	73	74

Medium-size geared hoists are suitable for more extensive d work, or mines of small tonnage, to say 500 ft in depth. They ar adapted for hoisting with buckets, light cages or skips, at speeds of 4 per min (Table 2).

Large geared hoists may be self-contained, or with engines and ported on independent bed-frames. They are especially suited heavy loads at moderate speeds, up to say 1 500 ft per min; hence, tageous for slopes or inclines, where high speeds are not permissib these conditions, geared engines give better steam economy, due to hi speed and ability to use drums of large enough diam to prevent und stresses in rope (Art 14). Geared hoists are useful where economy of and foundation is an object. Their cost is 35 to 50% that of direct-a for same hoisting load.

Constant-running geared hoists are sometimes used, as in the Michig copper districts. Two to 4 drums, serving as many compartments, are clutches, lowering being done by brake. By using a flywheel and Corliss economical working is secured, provided the drums can be kept in fairly cont ation. If made reversing, these engines evidently lose their advantage.

mates, cost may be taken at 10¢ per lb at factory.

irect-acting Steam Hoists

ıcting hoists are useful for large output, or for ng speeds. Besides the advantage of eliminating w speed of stroke permits use of Corliss or other n. Though usually designed for greater economy first cost is higher, and they should not be used for o ft, unless output is large.

ines have a limited application. Their high cost is expensive, and large loads are hoisted in rapid suc- When not operated condensing (condensers often ting service), their economy is but little better than g into account the intermittent running. They are vin tandem-compound. Though more costly, the because in the cross-compound the high-pressure gh to start the load when low-pressure cylinder is on ın economical ratio of cylinder volumes. Throttle signed so that, in starting and until full speed is steam at such pressure as will give it a starting effort is is done in 3 ways: (*a*) By exhausting h-p cyl into ing l-p cyl with steam at proper reduced pressure exhausting h-p cyl into the receiver and cutting off ı then receives steam at required pressure through a g receiver with steam at the reduced pressure for it also the h-p cyl. First method gives the best ım economy. Third method is simplest and requires in tandem-compound, cylinder ratios can be pro-

lor best operation is a mooted question. Though relation inder areas should be such that half the work is performed ys practicable with hoisting engines, on account of adverse ame of the h-p and V that of the l-p cyl, then the ratio of $V \div v = 0.85\sqrt{R}$ to $V \div v = \sqrt{R}$, R being ratio of expan- R^2).

STANFORD LIBRARIES

Area of l-p cyl is first calculated as if all the work were to be done in Approx diam of l-p cyl is found by:

$$D^2 = \frac{8\,500 \times \text{horse-power}}{\sqrt{p} \times N \times S}$$

in which D = diam of l-p cyl, p = gage pressure, N = rev per min, S = For cross-compound engines the horsepower would be that required for period, because during acceleration the h-p cyl is operated at late cutoff mitted direct to l-p cyl. For twin tandem-compound engines the horse that required during full-speed period.

Cylinder diameter for each cyl is found by:

$$\text{Area of cyl} = \frac{\text{horse-power} \times 33\,000}{\text{m e p} \times \text{piston speed}}$$

$$\text{Mean total pressure} = \text{terminal pressure} \times (1 + \text{hyp log } R)$$

R = nominal ratio of expansion r in h-p cyl = length of stroke in ft ÷ cu

$$\text{Mean effective press (m e p)} = \text{mean total press} - \text{back pres}$$

$$\text{Absolute initial press} = \text{abs terminal press} \times r$$

$$\text{Total expansion in both cyls} = \frac{\text{abs initial press in h-p cyl}}{\text{terminal press in l-p cyl}} \div$$

First calculate area of l-p cyl for doing total work. Terminal press in l-p c from which R is computed for l-p cyl, and mean total press is found from m e p from Eq 4, the abs back press being assumed. Area of l-p cyl is fou If half the work is done in l-p cyl, the m e p would be half that found from E total press is then recalculated. From Eq 3 the value of R for l-p cyl is obt recalculated value of mean total press and the terminal press for l-p cyl. for l-p cyl (Eq 5) is equal to terminal press in h-p cyl, assuming no drop betw R for h-p cyl is then equal to abs initial press at throttle divided by termin cyl. Compute mean total press in h-p cyl from Eq 3, and m e p from Eq 4, in this case being equivalent to terminal press in h-p cyl or initial abs pr Area of h-p cyl is then calculated, or area of h-p cyl may be quickly foun area of l-p cyl by R for that cyl. In above calculation no account is take compression, drop between cylinders, nor area of piston rod. To cover th m e p of each cyl is multiplied by a DIAGRAM FACTOR, which may be tak compound hoisting engines.

Examples of compound cylinder ratios. Old Dominion Copper C tandem condensing, 17 and 31 by 48 in, ratio of areas 1 to 3.4; 20 and 37 by to 3.45. Copper Queen Consol Mining Co, Ariz, twin tandem condensing, 48 in, ratio 1 to 3.08. Homestake Mining Co, So Dak, duplex cross-compoun 28 and 52 by 42 in, ratio 1 to 3.47. Fig 7. Band Brake

Post brake requires a smaller movement for necessary clearance
ring. Also, the load is always carried by the anchorage, regardless
in which the rope winds upon drum. Brake frames 2.5 ft radius or less may be pivoted at lower ends, and operated by bell crank and rod (Fig 8). Those over 2.5 ft radius should have a PARALLEL MOTION, and are then supported by sliding shoes moving on the sole plate, or by swinging links (Fig 9). Post brakes increase first cost of hoist 4 to 8%.

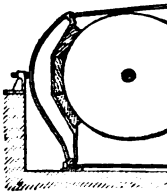

Fig 8. Post

Clutches are of jaw or friction type. JAW CLUTCH is simple and safe, but, because of its positive action, both drum and engine must be at rest, or nearly so, when clutch is thrown in gear, and the two parts of clutch must be in certain
tions before they will mesh. It is suitable where hoisting is generally in bala

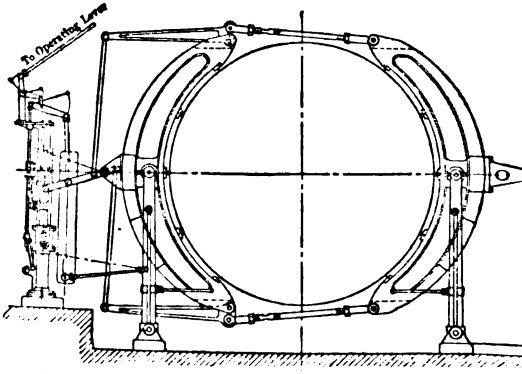

Fig 9. Parallel-motion Post Brake, Operated by Compressed-air Cylinde

one level. FRICTION CLUTCH is preferable where relative positions of cages
frequently, or a nice adjustment of distance between them is necessary. It
to general mining purposes. CONE FRICTION CLUTCH is satisfactory for drun

rger drums. But, with large drums, heavy loads, or high m-shaft bearings and friction on thrust pin cause trouble. Ex- ating rust haft. rated rrion rwise ected

6. Equalization of Hoisting Load

Load equalization deals with the varying weight of hoisting rope, which in deep shafts may exceed net load of ore. It economizes steam consumption, and reduces size of cylinders and therefore first cost of engine. Usual methods: 1, Conical drum; 2, Reed and flat rope; 3, Taper rope; 4, Tail rope; 5, Koepe or

y, the varying radius of a conical drum should be moment is constant. But this is true only when the ace is a curved line. Curve-faced drums are costly e not used. A single, straight-faced cone gives per- ginning and end of hoist (Fig 15); moments at all the one ent ing all nly mi- ght and wn, ble aft. ical vice ums. n of not (Art

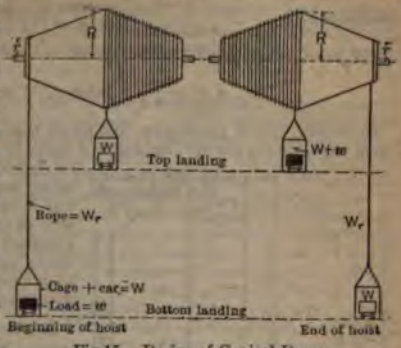

Fig 15. Design of Conical Drum

rge end of drum, ft; r = radius small end of drum, ft; op and bottom landings, lb; W = wt of cage and car, or

litions, the algebraic sum of the static moments in the two ages at top and bottom of shaft must be equal:

$$) r - WR = (W + w) R - (W + W_r) r \qquad (7a)$$

whence, $$R = \frac{r\,(2\,W_r + 2\,W + w)}{2\,W + w} \qquad (8)$$

in which R is the only unknown quantity. Since rope weight appears in only two terms of Eq 7a, the drum as designed equalizes only for the assumed depth of shaft. Width of drum depends upon depth of shaft, size of rope, and angle of drum face. For angles under say 30°, the horizontal pitch of grooves needs not be more than ¼ to ¾ in greater than rope diam; for large angles, pitch may be 2 to 2.5 times rope diam, to make grooves deep enough to prevent displacement of rope. Number of grooves = rope length divided by mean circumference of drum. Cylindro-conical drums (Art 5) may be used for deep shafts, to avoid excessive width of drums (Fig 17). This is at expense of equalization.

Passing point of cages. Let S = distance of passing point below surface, ft; l = distance between top and bottom landings, ft; d and D = respectively small and large diam of drum at bottom of groove, ft; a = rope diam, ft; n = number coils of rope on one drum with cage at top s (2 or 3 extra coils at each end being usually allowed).

$$\frac{l}{\left(\frac{D+d}{2} + a\right)} = \frac{2\,l}{\pi\,(D + d + 2\,a)} \qquad (9)$$

elow middle of shaft) the number of rope coils on *abce* = ssing point is reached when drum has made half the revolu-

STANFORD LIBRARIES

tions required for a complete hoist, and both ropes are winding on me
of rope unwound from $bfgc = S$, whence:

$$S = \frac{\pi\,(bc + fg)}{2} \times \frac{n}{2}, \quad \text{and} \quad \frac{bc + fg}{2} = \frac{\frac{d+D}{2} + D}{2} = \frac{3D}{}$$

Substituting, $$S = \frac{\pi n}{8}\,(3D + d)$$

If D and d be taken as diam of rope coils,

$$n = \frac{2l}{(D+d)}, \quad \text{whence,} \quad S = \frac{l}{4}\,\frac{(3D+d)}{(D+d)}$$

To increase rate of acceleration, and attain max speed sooner, dru
coned steeply for a few rev, remainder of drum being cylindrical. T

Flat rope (Ar creases the winding radiu an increment equal to hence, the result is theore and same calculations ap rope and conical drum. flat rope, practical consi thickness for a given widt winding increment so tha even more imperfect th drum. Advantages of r and lower first cost than for drums; elimination of fleet angle vantage: lack of the steadying effect on engine produced by the l

Design. Diam of reel hub d should be at least 60 times the rope th selected rope of proper strength, following are the relations betwee winding diam d and D, length of rope l, and its thickness t, all in between inner and outer surface of coiled rope $= lt$; whence,

$$lt = 0.25\,\pi\,(D^2 - d^2)$$

and, if $D = xd$, $$lt = 0.25\,\pi\,d^2\,(x^2 - 1)$$

whence, $$d = \sqrt{\frac{lt}{0.25\,\pi\,(x^2 - 1)}}$$

in which $x = D \div d$, found from Eq 8. Knowing d, $D = xd$.

Example. Rope, 2 000 ft = 24 000 in of 4 by ¾ in, 2.65 lb per ft 6 000 lb; skip, 3 000 lb. Then $x = (2 \times 3\,000 + 2 \times 5\,320 + 6\,00$ 6 000) = 1.88. Substituting in Eq 13:

$$d = \sqrt{\frac{24\,000 \times \frac{3}{4}}{0.7854\,(1.88^2 - 1)}} = 67.2 \text{ in} = 5.6 \text{ ft}$$

Hence, $D = 1.88\,d = 1.88 \times 67.2$ in $= 10.52$ ft.

Tapered rope (Art 14) assists more in solving problem of deep hoisti ing the load. Theoretically, the rope is of constantly decreasing s maximum diam and total wt are smaller than for rope of uniform se

ced load at beginning of hoist is decreased; with conical ed.

mum size of cylinders can be used, but engines must be reversible, beca is required to raise the excess weight of the counterpoise as the unbalanc With a given engine serving a single compartment, net load and daily increased. This method is of especial advantage for electric hoists, if p on peak load basis (Sec 16). By using a tail rope perfect equalizatio obtained, and unbalanced load at all times is one-half net weight of ore.

8. Hoisting Engine Calculations

Factors for general case: 1. Daily output required governs nu per day or shift. This, in turn, depends on load per trip, as dete of car (or other local conditions), depth of shaft, type of plant, and delays and handling men and supplies. 2. Gross load = wt of o

determined by wt of ore, car and cage, multiplied by vert dead into live load, plus weight of rope. Rope ned, and one or more approximations made. (For ; ropes, see Art 14.) 4. Max unbalanced load, when shaft, equals wt ore + rope. 5. Total time for a e factors must be harmonized for selecting type and r conditions; geared hoist for low, direct-acting for

For SINGLE-COMPARTMENT SHAFT, this covers down bottom and top, for caging cars; or, with skips, for is also holds good, in general, for double-compart-ent drums operated by clutches. For DOUBLE-COM-in balance with fixed (keyed) drums, or single drum the total time per load is the elapsed time from the om on down trip until it stops at top on up trip.

th best track arrangements, takes 7 to 8 sec; better , which may be greatly exceeded when loading facil- and power-operated loading chutes, delays may be 10 sec minimum should be allowed. Larger allow-

NOTE. — In hoisting with fixed drums, since load-imultaneously, the longer time, whether at top or r, and one allowance for delays suffices. Besides the m 20 to 40% of each shift is usually occupied by supplies.

od. Time per trip includes periods of acceleration, tion. Acceleration and its period vary widely. For depth, acceleration is from 2 to 10 ft per sec per and large tonnages, it may be 12 to 15 ft. At latter ay run into retardation period, with practically no with conical drum or reel). Uniform speed period and hoisting speed. With geared hoists max speed min. With direct-acting hoists, 4 500 to 5 000 ft ned. Speeds of 2 000 to 3 000 ft are common. Re-ceeds that of acceleration.

per sec per sec; v = mean velocity, ft per sec; v_1 = = hoisting time, sec; t_1 = time of acceleration, sec; c; h = depth of shaft, ft; s = distance passed over hen, $t_1 = v_1 \div a$, and $s = v_1^2 \div 2a$; and if time and d retardation be assumed equal,

$$t_2 = \frac{h - 2s}{v_1} = \frac{h}{v_1} - \frac{v_1}{a}$$

$$+ t_2 = \frac{2v_1}{a} + \frac{h}{v_1} - \frac{v_1}{a} = \frac{v_1^2 + ah}{av_1}$$

$$\frac{ahv_1}{v_1^2 + ah}, \quad \text{whence} \quad a = \frac{vv_1^2}{h(v_1 - v)} \qquad (14)$$

Codely, 2 289 ft in 55 sec. Rhodes Rotherham, 1 650 ft in 45 sec. At Rosel England, speed of 5 100 ft per min is on record.

Usual ranges of hoisting speed are as follows: SMALL GEARED HOISTS, 45 min; large, 900 to 1 200 ft. SMALL DIRECT-ACTING HOISTS, 1 000 to 1 5 large, 2 500 to 3 500 ft.

With fixed output, speed and load are dependent upon each other. I hoisting speed per min; T = output, tons per hr; W = net load, tons; shaft, ft, and t = caging time, min; then,

$$V = \frac{hT}{60W - Tt}$$

Engine details. Minimum diam of drum depends on diam of rope (maximum diam, on hoisting speed required and piston speed of engine. R ING, from 1 : 3 to 1 : 6. PISTON SPEED rarely exceeds 650 ft per min; fo 500 ft. RATIO OF CYL DIAM to length of stroke varies for geared hoists 1 : 1.67; ratios of 1 : 1.25 to 1 : 1.33 are common. For direct-acting ho usually from 1 : 1.3 to 1 : 2.66. FRICTION ALLOWANCE for engines, shea guides is generally lumped to cover all these items, including windage. Futers (4) assume starting friction of engine as 25% of wt of one cage + co running friction as 0.6 of this or 15%, and shaft friction and windage as 10 all these items are not effective until after starting, it is customary to take ance at 20% for direct-acting and 25% for geared hoists. Following frictio were measured at three Butte (Mont) shafts, when hoisting from depth max speeds of 3 000 to 3 500 ft per min (6, p 837).

	In balance	Out
Speculator shaft	21.1%	
High Ore shaft	23.0	
Diamond shaft	29.0	

These percentages are in terms of indicated work of the engines, the diffe values when hoisting in and out of balance showing that shaft friction at speed is much greater than engine friction. In these cases the engine fric probably less than 6% (6).

Effective crank radius is taken at 0.58 of full crank radius for engines 87.5% of stroke, which is about as late as is practicable. This enables c start the load, when cranks at 90° apart are in their most disadvantageous

Steam pressure. INITIAL PRESS is assumed for small hoists in at 80 to 100 lb. For simple, non-condensing hoists, assume 100 pound, 125 to 150 lb. (NOTE. — Hoist should be designed to start pressure, to take care of emergencies.) MEAN EFFECTIVE PRESS not affect size of cylinder necessary to start the load, but must when engine is up to speed with shortened cutoff. I indicator cards, approxima be calculated by:

$$p = 0.9\,[c\,(p_i + 14.7)$$

in which: p = m e p (gage steam press (gage); b = a press (for hoisting engines c = constant depending on off; 14.7 = atmos press at 0.9 is the diagram factor

Table 8 gives data of large with approx costs.

9. Electric-driven Hoisting Engines

(See Sec 16, "Applications of Electric Transmission for M

10. Hoisting with Compressed Air (See also Sec

Compressed-air hoists have same general construction as s small-scale work standard geared hoists are used (Table 8). operation, large expansive-working engines require cylinders Cutoff is later, clearance volume is reduced to minimum, and ports are required, since at same pressure the density of ai steam. SMALL HOISTS, running intermittently, give no trou of moisture in exhaust ports, as cylinder walls and passages h normal temp. But, for economy, the air should be reheated. acceleration, air is admitted at practically full stroke, and pc throttle. IN LARGER HOISTS, with expansion gear, expansio because, since there can be no condenser, the terminal press for proper exhaust. Owing to rapid drop in temp of expand done is less than with steam; that is, the adiabatic curve of a steam, with corresponding decrease in mean effec press. Hen cutoff must be later (Sec 39). On the other hand, the theore expansion is never reached in practice, because of transm cylinder walls, compression in clearance spaces, and presence air. Loss in efficiency due to incomplete expansion can be red expans[illegible] in high-press cyl at 0.9 stroke (mi

ing between cylinders to initial temp, the loss in t one-half that of a simple cylinder, or a saving of entering high-press cyl.

l air. See Sec 39 for theory, and results of work with . Table 9 gives relations between initial and terminal nts of cutoff (9). Corrections are necessary for clearance off being found by dividing the sum of cutoff plus clear- earance. Thus, if stroke is 5, with cutoff at 0.2 and clear- of cylinder plus clearance is $(5 \times 0.05) + 5 = 5.25$; the $+ 0.25 = 1.25$, and actual cutoff is $1.25 \div 5.25 = 0.23$. volume of air at cutoff is increased by the clearance, the culated on basis of nominal cutoff.

Cylinder volume. Work per stroke is calculated from ft-lb of wor revolutions of engine. This, with initial and final pressures is subst for partial or for complete expansion (Sec 39), which is solved for initi pressed air per stroke = theoretical cylinder volume. This is correc according to type of engine, and the proper ratio of stroke to diam is de volume of air ÷ volume at end of expansion = per cent of cutoff.

Volume of compressed air required = volume of air per st above) × number of strokes, remembering that there are 4 str tion in a duplex hoist. Volume so found is reduced to free air (Se gives volume of free air per min per indicated hp, for different reheating, and at 60° initial temp. These values do not incl corresponding to piston clearance (see above).

Table 11. Cubic Feet of Free Air per Minute per Engine I H P

Point of cutoff	Gage pressures, lb							
	30	40	50	60	70	80	90	100
1	23.3	21.3	20.2	19.4	18.8	18.42	18.10	17.8
¾	18.7	17.1	16.1	15.47	15.0	14.6	14.35	14.15
⅔	17.85	16.2	15.2	14.5	14.2	13.75	13.47	13.28
½	16.4	14.5	13.5	12.8	12.3	11.93	11.7	11.48
⅓	17.5	15.2	12.9	11.85	11.26	10.8	10.5	10.21
¼	20.6	15.6	13.4	13.3	11.4	10.72	10.31	10.0

Quantities of free air in Table 12 are based on actual runnin hoists. As such engines seldom run more than ¼ to ½ the tin capacity of ¼ to ½ the volume given is sufficient, provided the age capacity, and the time per trip is short.

30 hp. Engine runs at constant speed, and is controlled by a governor, admission of gas at every alternate revolution, or shuts off gas entirely as sp larger capacity, 4-cycle engines with 2 to 8 cylinders are employed (12). T cal and similar to the ordinary automobile and marine type. Since rot high, double-reduction gearing to drum shaft is desirable. Speed may be v tling the gas, and advancing or retarding the spark. Chief advantages of m engine are: variable speed, thus allowing slowing down between hoists an up the load; power is more uniform throughout each revolution; large fly nated; engine is more easily started from rest; self-starters, as for autor may be applied; less danger of stopping while hoisting.

Double-drum gasolene engines for hoisting in balance have sp and gears. In one form, crank shaft is at right angles to drum sha it by diametrically opposite bevel pinions, meshing with a gear or Each pinion is loose on shaft, and is driven by friction clutch.

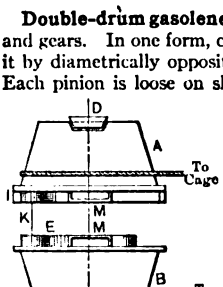

Fig 24. Arrangement of Clutches, Double-drum Hoist

locking device only one clutch at a thrown in gear; this rotates drum shaft tion, and throwing in the other clutch opposite direction. Drums are keyed controlled by clutch.

Fig 24 shows diagrammatically an arrange ing in balance with 2 drums, the engine ru ously in one direction (13). Each rope wi drum, the drums being thrown in alternate D and D_1. Internal gear I, driven throug drum A, is connected by pinion shaft K with which is thrown in or out of gear with drum With drums at rest to hoist cage A and low is thrown in and D_1 out, while both clut gear. Drum B will then rotate in opposi drum A. Clutches M may be dispensed necessary to change relative positions of ca is used to pick up load while engine is runni

Rating and capacity. Rating is us of indicated hp. Lifting capacity and h also depend on quality of engine and ca nance. Let L = load or lifting capacity; HP = rated hp of engine efficiency of hoist; S = hoisting speed, ft per min; then,

$$L = 33\,000\,eHP \div S$$

Up to 10 hp, e may be assumed as 0.5 to 0.6; for larger engines, 0.6

At Blackwood Colliery, L. V. Coal Co, Penn, a gasolene hoist hauls c slope, at 40°. Wt of car and coal is approx 4 000 lb, rope speed, 200 ft per loose on shaft, and driven by band friction clutch. Engine has 4 cylind with gears for reversing direction of drum rotation.

12. Hoisting from Deep Shafts

Deep hoisting is taken to mean hoisting from depths greater tha Because of the time required to hoist from great depths, and inc of rope weight to net load, both speed and load must be increased given tonnage. Great length of rope requires large drums, the mas of which make special problems in the design. The highest grade are requisite. For depths to say 4 000 ft, cylindrical drums with form section are suitable, but better economy is obtainable with ho having special features for deep winding. In each case the resul adjustment as to operating expense, efficiency, and capital outlay,

sed for deep hoisting are: (*a*) HOISTING IN A SINGLE l ropes of uniform section or tapered; (*b*) WHITING KOEPE SYSTEM WITH TAIL ROPE; (*d*) HOISTING IN h rope, one suspended at half the depth and one at aded and dumped simultaneously, lower skip dis- h the upper skip is filled; (*e*) HOISTING IN TWO OR r stage hoist either on surface or underground.

t. For depths of 4 000 to 4 500 ft, conical drums may be used without exceeding practical limits for 000 ft taper ropes become necessary, with conical m section rope, the slope of drum face for equality angerously steep. Also, the weight and moment of ery great. For hoisting 50 tons per hr from 5 000 ft, 42) calculate an engine of following dimensions: small m, 24 ft; cyls, 38 by 48 in; max speed, 60 ft per sec; g skip, 30 sec; net load, 6 100 lb; taper rope in 4 sec- 375 in diam, the other 3 of 1 400 ft each being 1.0625, pectively; total weight of one rope 11 600 lb, with rm-section rope were used, diam would be 1.4375 in; im pressure is assumed at 150 lb. For same output, 4 times that required for a depth of 3 000 ft. Hans sting engines more than 3 times as large are required om a depth of 6 000 ft as from 3 000 ft.

d rope for hoisting in a single lift from vertical depth of C. W. Comstock (15), as follows: wt of ore, 15 000 lb; h wires of tensile strength of 270 000 lb per sq in, 1.13 in t upper end; wt, 41 240 lb. ROPE has a varying section, t all points, and is calculated by formula

$$d = d_0 e^{\left(\frac{\delta x}{f}\right)} \tag{25}$$

from lower end; δ = wt per cubic unit of rope; f = unit e, or total area of the circumscribed circle; e = base of d. Weight of a length x of this rope is:

$$W = (Q + q)\left(e^{\left(\frac{\delta x}{f}\right)} - 1\right) \tag{26}$$

wt of skip. The smallest diam of drum is taken as 1 500 s (0.084 in), or 10.5 ft. Allowing for angular position of on, acceleration, and bending stress, the total unit stress equivalent to net safety factor of 2.88. DRUM is designed stant, when winding a rope of constant unit stress. Equa- surface is:

$$\frac{{}^{n}+1] - 2A^{2n}\left\{A^{y_n} - 2\,(y_n - 1)\,A^{3(\quad+1)}\right.}{{}^{n}+1] - 2A^{2n}\left\{A^{y_n} - (y_n - 1)(A^{2(\quad+1)} + 1)\right.} \tag{27}$$

bove or below mean radius; if below, n is considered nega- n radius of drum, in; δ = 288 lb per cu ft for steel rope with in; f = unit stress of nominal cross-section of rope, or cle circumscribing rope; y_n = ratio $\rho_n \div R$, in which ρ_n is or below mean radius. Mean radius is radius of coil or passing point of skips in the shaft; $y_{(n+1)}$ = ratio of radius to the mean radius.

landing and sheave is neglected:

$$R = \rho_{-n}\frac{Q + 2q + p_{-N}}{Q + 2q} \tag{28}$$

end of drum, and p_{-N} = weight of one rope equal to depth

STANFORD LIBRARIES

Since R is the arithmetical mean of any two radii, at same number of rev
and below R, then, $2R = \rho_N + \rho_{-N}$

in which: ρ_N is the radius of large end of drum and ρ_{-N} is fixed by assum
diam of large end of rope to diam of the small end of drum on which it wind
from Eq 28, and ρ_{-N} from Eq 26. With R and ρ_{-N} known, ρ_N is found fr
calculating the intermediate radii from Eq 27, start at mean radius R, as
to simplify calculations. For first revolution, $\rho_n = R$ and $y_n = 1$; for
tion the value of $y_{(n+1)}$ found for the first revolution becomes the value of
Only half the number of radii need to be calculated, because those on the o
R may be found from Eq 29, which may be written, $2R = \rho_n + \rho_{-n}$.

Total number of revolutions for one trip is the same as for a cylindrical drum
or if N is the total number, then, $N = H + 2\pi R$

in which H = total depth of shaft.

Detailed design is required to determine exact width of drum. In this c
(15) calculates drums 14.14 ft diam at small end, 49.5 ft diam at large en
diam of 31.82 ft. Width of each drum is approx 24 ft, requiring that th
behind the other, and connected by vertical walking beams or operated
cranks. An average speed of 3 000 ft per min is assumed; also an acceleratio
ing skip of 16 ft per sec, corresponding to 4.5 ft per sec acceleration for loaded
starting moment to be overcome by engines is calculated at 3 324 300 ft-lb
unbalanced load times mean radius, or 240 000 ft-lb; moment due to accele
which consists of 2 skips, 1 rope, and ore, or 176 200 ft-lb; and moment du
tion of 2 drums and 1 rope on one drum, or 2 908 100 ft-lb. Each drum
weigh 193 000 lb. Compound cylinders are calculated: hp cyl, 32 by 96 in
96 in, a pair of cylinders being at each end of drum shaft. Initial steam pre
ing, 150 lb. Acceleration requires 5 sec, the engine being worked compou
mainder of hoist. Total time required per trip, from start to stop, is 4
made up of 5 sec acceleration, in 1.25 rev; 63 sec retardation, 16 rev; 205.
speed, or 102.75 rev at 30 rev per min. Allowing the remainder of a 5-r
25.5 sec, for loading and dumping, 12 trips per hr are made, or 12 × 7.5 to
Form of drum, as calculated above for a taper rope, approaches a true con
closely that a cone may be used without seriously affecting conditions.

Whiting system with tail rope (Art 6) requires rope of uniform s
is not applicable when the depth is such that the useful strength of th
small for a load required to give the output. With rope of high tensile
system has advantages to a depth of say 6 000 ft, especially if hoistin
bottom only. A tail rope (Art 6) is necessary, giving constant load
the hoist. This has the advantage of lower first cost; the engines are
less energy is required to accelerate the comparatively light driving

Koepe system with tail rope (Art 6) has same advantages as t
as to low first cost and elimination of fleet of the rope. The large s
eter requires larger engines to overcome the static moment on start
Koepe sheaves are better adapted to constant-torque electric ho
steam hoists. With large cylinders and relatively low rotative speed
of large drums is an advantage in steadying the engine impulses.

Tandem system (Fig 25) consists in having 2 skips in the same com
upper skip with a rope equal to half the depth of shaft, the lower with its
to bottom of upper skip. Upper skip receives its load from pockets at m
shaft, into which the lower skip dumps. Both are loaded and dumped si
The upper rope carries its own weight and that of both skips. Both ropes m
The drums need be only large enough to hold rope equal to half the total
equation for the ratio of end diams of conical drums (Art 6) must be modifi

Let W_r = wt of whole rope; W_l = wt of lower section; w = wt of ore
and W = wt of both skips; then, for equal static moments at beginning and

$$r(W_r + W + w) - R(W + W_l) = R(w + W + W_l) - r(W + W$$

whence $$R = \frac{r(w + 2W_r + 2W)}{w + 2W_l + 2W}$$

smaller than for hoisting with a single lift, and moment of . There is an economy in steam consumption of about , and the hoist is smaller, with consequent lower first of extra loading pockets and shaft arrangements.

3) requires 2 engines, one hoisting from the bottom intermediate station, from which the other engine

bending stresses are not considered. Mining regulations of the quire that the factor of safety shall be at least 6, bending stresses a disregarded. R. B. Greer (16) recommends a sliding scale facto depths exceeding 2 500 ft, since the elasticity of a long rope comp for stresses due to starting with slack rope, the actual weight of cag and bending stresses being practically constant for all depths.

Determination of proper size and quality depends upon th and depth of shaft. For same ultimate strength, plow-steel rope c more than cast-steel; while, for the same weight, plow steel is st 10% for the smaller sizes to 35% for the larger. Hence, it is e heavy loads and deep shafts, where rope weight is a large part of steel or extra plow steel should be used, especially as bending s same for both cast and plow-steel rope of same diameter. Rc To the known load stresses add wt of rope assumed to be the co bending stresses for this rope over smallest advisable sheave or dr by safety factor required, and compare with ultimate strengths in ing a rope the strength of which is nearest that calculated. With recalculate bending stress and weight of rope, and check result fixed economical ratio between bending stress and load. In sha bending stress may economically be 0.33 to 0.40 of total rope stre shafts such a condition leaves too little of the rope strength for weight of rope is deducted. SELECTION OF ROPE requires a know tions under which it is to operate. Steel is always better than and plow or extra crucible steel is generally preferable to ordinary For same strength, a plow-steel rope may be employed on smalle wrought-iron rope, and on sheaves of same diameter as ordinary s slopes, inclines, and rope-haulage systems, 6×7 rope is better th Lang lay is preferable for endless-rope haulage where car grips vertical shafts 6×19 ordinary lay is standard American practice. with a greater number of smaller wires is not justifiable except ir where the size of the drum or sheave is limited. In a shaft in regularly hoisted, it is generally advisable not to use rope smaller t for psychological reasons, regardless of actual strength required.

Wear and durability of rope depend upon diameter of sheav speed, conditions causing wear or abrasion of the outside wires,

lities are practically independent of the load, so tic limit of the wires. Sheaves or drums of too outer wires. If wires show clear fracture before h, either the sheave is too small or the wires are ure. Tables 22 and 23 (21) show effect of diam- f rope. High speed causes rapid wear; excessive ystallization of the steel. If sheaves have rough de, wear on surface wires is severe, due to chafing and between the rope coils on ungrooved drums. pend upon efficiency of lubrication, and whether y shafts, if rope is well lubricated, and sheaves corrosion and wear of interior wires is negligible. cid, corrosion of wires determines the rope's life.

6 × 19; 2 diams of wire were used in the strands, 0.114 and 0.076 in; te wires, 257 600 lb per sq in; safety factor, 11.2. Work done by each rope ft-tons; distance run, 21 790 miles; cost per ft-ton, 0.0001708¢. Bes was by a rope not included in the above. This was a 6 × 19 Lang lay 0.094 in diam, with total area of 0.7912 sq in. Tensile strength of wire sq in; reduction of initial strength after 6 months was 35%. Initial sa At end of 357 days the work done was 1 669 935 634 ft-tons; distance miles; cost per ft-ton, 0.000073¢. Lowest cost per ft-ton is apparently high-class heavy rope, carrying a heavy load and working steadily (22).

At a slope in West Pittston, Pa (23), 1 800 ft long, with pitch varying 21 ropes were used between 1893 and 1903. They were from 1.25 to 1⅜-i ent grades of steel and number of wires, some Lang lay and some of ordina life was 6 months; coal hoisted per rope averaged 61 500 tons. 6 × 19 r or better service than 6 × 7, probably due to the fact that at vertical an rollers and sheaves of too small a diam were used for a 1⅜-in. 6 × 7 rop the rope was bent 15° over a 5-ft sheave, at another 24° over 4 2-ft rollers.

Care of hoisting ropes. Avoid kinking or nicking the wires tion and use. Frequent inspection is essential. Where men are inspection should be made daily, and a thorough inspection w rope socket or capping is attached directly to cage, and landing c the rope close to the socket will often first show wear or broken slack rope may cause sharp bends at that point. When this occ of rope should be cut off at regular periods, and a new socket j there is enough headroom, a few feet of chain between rope so draw-bar is advantageous, and in some cases required by law. rope end for end, at the expiration of half its useful life, is also so that if wear occurs at any particular point, it will be distributed length of rope.

Lubrication must be efficient, to prevent wear and corrosion minimize surface abrasion. In severe service proper lubrication rope's life 75 to 100% (24). The core should never be allowed enough to absorb moisture. A good lubricant should be chem and of such character and consistency that it will penetrate the core; it should not run nor drip off, nor be so thick and sticky as on the rope or in sheave grooves. Some lubricants, apparently soon harden and flake off, especially in cold climates. Raw linseed runs off easily. More body is given by adding lampblack or fine A common mixture is 1 bbl pine or coal tar plus 1 bushel slake hot. Lime gives body and neutralizes acid often present in c pine tar, tallow may replace the lime. This mixture is sticky an in cold climates does not penetrate well between the wires. Pet vaseline mixed with fine flake graphite and applied hot is good. facturers have rope dressings for different conditions. Lubri applied at intervals of say 1 to 3 weeks, depending on conditions; first cleaned of dirt and gummed lubricant, by passing it through kerosene and scrubbing with stiff-wire brushes.

Splices are not permitted in hoisting ropes used for raising or lowerin haulage, aerial tramway, and power transmission rope, splices may be as strong as the rest of the rope (Fig 42). For a running rope, the splice s 20 ft long for 0.5-in rope, increasing to 30 or 40 ft for 1.25 and 1.5 required are: hammer and sharp cold-chisel, pair of strong nippers, st 2 rope clamps (or small hemp rope slings with sticks, Fig 42, *e*), a knife a copper or lead mallets. A bench vise is convenient. To splice (Fig the rope 20 ft or more, and mark center of lap on each end with string or ch lay each end to center mark, and cut off hemp core (*b*). 3. Interlock the of each end alternately, and draw together until center marks meet

it closely with opposite strand 1 of other end, laying
nd proceeding thus until all but 12 in of strand 1 are

cut off hemp core. Separate individual wires (for this a piece of small p'pe Clean well with turpentine and wipe thoroughly dry. Soak for 5 min i 0.5 water, 0.5 HCl. Bind the loose wires together at top (*do not bend bac* over them and release ends of wires. Close base of socket around the rope

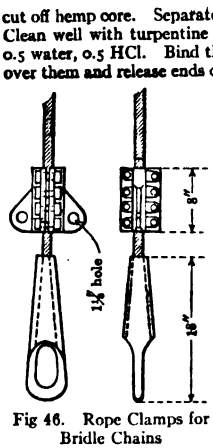

Fig 46. Rope Clamps for Bridle Chains

pour the basket full of molten spelter, **not** Another method (25) consists in dusting the instead of cleaning with dilute HCl, and usin composed of 60% lead, 30% tin, 9% anti bismuth. Antimony increases hardness and fusion temperature, also expanding slightly i heat of molten white-metal does not affect st W. Routledge (26) on testing 28 wires remove and the same wires from a different part of found the strength to be unaffected by ab The breaking of the wires close to socket bending at this point caused by slack rope (s rope").

Wire rope clamps, for attaching bridle c to rope, above socket, are more commonly us at metal mines; laws of most coal district Vulcan Iron Works makes the clamps shown i are usually of cast steel, but forgings are be grooved to fit the rope closely, and the bolts s tightened after the rope is under tension. clamps (27) show the ultimate strength against slipping to be about 10 c of area of the bolts securing the clamp.

15. Hoisting Sheaves

Construction. For diameters up to say 7 ft, sheaves may be of C I in one piece; larger sizes have C-I rim and hub, with W-I spokes. Tread or bottom of groove must be smooth and true, with a radius slightly greater than that of the rope. Grooves of large sheaves are often wood lined, to reduce wear on rope, the blocks being set with grain on end. Depth of groove and width at rim are 3.5 to 4 times the rope diam.

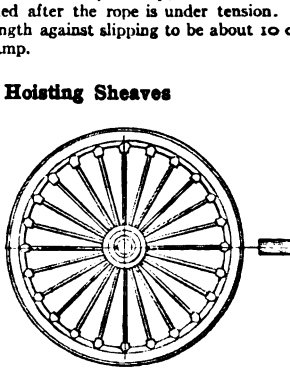

Fig 47. Wrought-iron Spoke

Spokes of W-I sheaves are cast into rim an and 48), making an angle of about 7° with pl Sheave shaft or arbor is solidly keyed in the ported in heavy bearings.

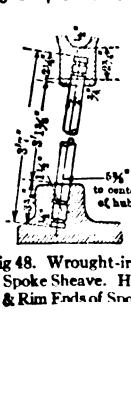

Fig 48. Wrought-iron Spoke Sheave. Hub & Rim Ends of Spoke

Bearings are of the post type (Fig 49), with th plane of base, or of the ordinary horizontal type design of headframe (Art 16). Post bearings either vertical or horizontal position, having the advantage that the resultant of the rope pull always falls approximately in bottom of bearing. Journals should be so proportioned that the unit pressure does not exceed 200 lb per sq in, to permit proper lubrication.

HEADFRAMES

16. Design of Headframes

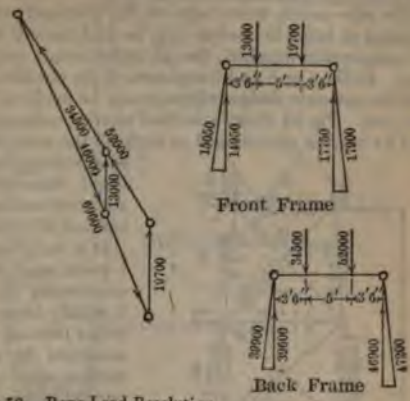
Types. Headframes are of the A-type or modifications of it (Fi
or of the 4 or 6-post type (Fig 58 and 55). The A-type is more e
material, and the stresses are all determinate. The 4 or 6-post typ
when the shaft compartments are not in line with engine; that
of drum is normal to long dimension of shaft. They are con
Penn coal fields, where the compartments are large and so require
overhang of sheave to line up its circumference with center of shaf
there are often 4 compartments in a row. Where a rock house or t
bined with the headframe, the 4 or 6-post type lends itself a little
to the construction.

General principles of design are the same as for any fram
Severe conditions of mining and great variation of load require
factors than ordinary structures, and ample thickness of section fo
bers, because of the exposure to corrosion at mouth of shaft, fr
air. Minimum thickness of section is usually specified as ¼ in to

Height is fixed by: elevation of cage landing or skip dump al
over-all height of cage or skip, when in dumping position; and allow
winding (Art 27). OVERWINDING ALLOWANCE depends chiefly on s
ing, type of engine, and drum diameter. It is usually specified
drum circumference, but with drums of 20 ft or more diam, and wh
discharged to bins or crusher at a considerable height above shaf
may give a prohibitive height of frame. For speeds under 500 ft
10 ft is ample, although it is better to allow more if convenient. Fo
a clearance of 25 ft, from rope socket to sheave center, is rarely exc
the landing is above the ground, and 35 ft where the landing is at
At the landing portals, bracing is arranged to allow ample room fo

Calculation of stresses. For A or 2-post frames, all stresses are
and are conveniently found graphically. Total stresses are due to: (*a*
or weight of the structure, and sheaves with their bearings (Art 15).
frame is approximated from that of a similar headframe (by a prel
mate) and divided equally among panel points. (*b*) WIND LOAD. W

or headframes which carry a housing, and at 50 lb
ection of the members if not housed. Wind loads
he joints of members. (c) LIVE LOAD, assumed as



50. Rope Load Resolution

ng strength of the rope (see also Art 17 and 18).
ne takes half the live load. With 2 ropes (hoisting

the sheaves are equidistant from the center and side posts. In th frame, it is sufficiently accurate to consider the live-load stresses as intersection of front post and back stays; although, in the structu resultant of the rope stresses may not pass exactly through this poi in the side panels takes none of the live-load stresses. Diagon assumed as being in tension only, in steel frames, whence the hori are compression members, though under certain conditions they ma sion. In the 4 or 6-post frame some of the stresses are statically in and for accurate design reference may be made to standard work ject (30). Fig 54 shows a method meeting ordinary requirements. and its bracing are assumed to carry all the wind and dead load, wind stresses in transverse bra stays. Since diagonals are cons sion members only, redundant omitted in calculations.

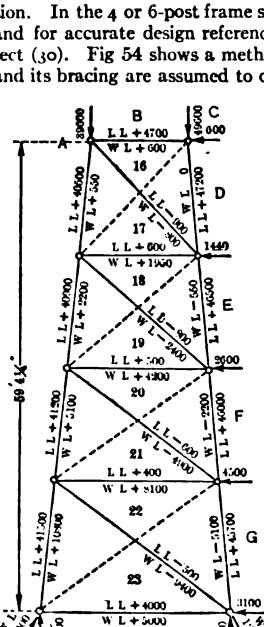

Fig 52. Headframe Stress Sheet, Projection on Plane of Back Stay

It is to be remembered that a whole must be sufficiently st overturning by wind pressure. is usually best to depend on w rather than on anchor bolts, w weakened by corrosion. Ma turning effect of wind will be i parallel to the shortest dimensi area. The total area in sq ft o exposed to wind, *on both windward sides* of frame, multiplied maximum horiz press per sq f press in lb. This may be taken trated horiz load, acting at the ure of the frame. It is resisted structure, including sheaves a multiplied by half the width o

The position of the center of closely approximated in any giv proportioning the width of ba allowance should be made to ca nal resultant of wind press and to fall well within the base area. lation is similar for a structure attached to the frame.

Graphic determination of stresses for an A or 2-post frame is shown in 53, in which the loading on one rope is assumed as half the rope's breaking st the other double the weight of skip, contents, and rope. Shaft, 1 200 ft deep; ore, 4 500 lb; 1-in plow-steel rope, 1 896 lb; breaking strength of rope, 76 o 6 ft diam. In Fig 53, the wind load on side of frame, combined with the the maximum stresses in front posts and bracing. Bracing in front and b takes none of the dead load. Weight of frame is estimated as 50 400 lb, ar to dead load, and wind pressure from the rear, as shown in Fig 51, give m at foot of back brace if the ropes should at any time be removed from the sh shows stresses in back brace due to live load and to wind pressure on one s posts are usually made normal to plane of front and back of frame. Combi tions at foot of one back post gives maximum uplift normal to the base maximum pressure of 61 900 lb, and a shear on anchor bolts at right an pressure (or tension) of 10 000 lb. Similarly for the front posts maximum sure on the base is 48 200 lb and shear 8 900 lb.

and the whistles to blow. The
be used as a speaking tube.

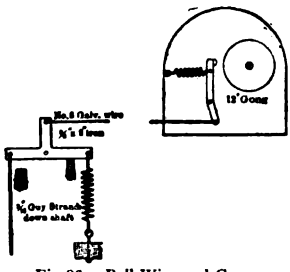

Fig 86. Bell Wire and Gong

This method is reliable, with
maintenance expense; not affecte
accidental signals cannot be given as in some electrical systems. No indicator can be used, as in electrical systems, to supplement bell signal. Cost for each station outfit (Fig 87), not including piping between stations, is: 300 ft signaling distance, $20; 800 ft, $25; 1 500 ft, $30; 2 000 ft, $40. In the Missouri lead district, a small whistle is often placed on the air line at top of shaft, which is blown by a hand wire from the shaft stations; a bell in engine room is sounded from the shaft mouth.

Fig 87. Pr
Gong an

Electric signal systems are of general application, but for reliability require careful installation and maintenance. There are 3 classes.

A. Low-voltage direct current, operated by wet, dry or storage batteries. Annunciator bells should be iron clad and waterproof, and heavier and more durable than house bells. Only the best rubber-covered double-braided wire should be used, and al down the shaft in metal conduit. Double-conductor twisted wire is good. are cheap and convenient, but are a source Small single-throw knife switches are bet buttons; or specially designed contacts, dirt and water, may be used. All the bel one circuit (Fig 88, *B*), so that the signal s tions and in the engine room. If only the an I engine room bells ring (Fig 88, *A*), co cause l by two stations attempting to si ously. Engine room and station bells a that the signal may be repeated from en necessary to signal from the cage at any po wires *a* and *b* (Fig 88, *B*) may be bare and lators on shaft timbers, the signal being m contact with a piece of iron or by pressir gether. In wet shafts this plan gives t batteries are rapidly exhausted. Fig 89 SIGNAL AND LIGHTING SYSTEM, at Geduld m (19), as arranged for sinking. T showing the connections represent double conductors.

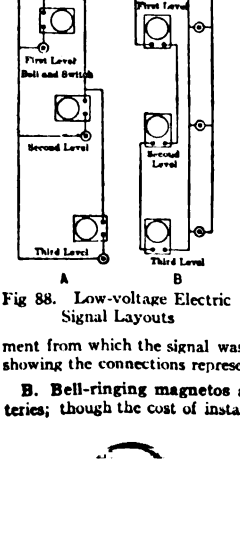

Fig 88. Low-voltage Electric Signal Layouts

B. Bell-ringing magnetos are excellent, as they do not become exha teries; though the cost of installation is much higher. Loud-ringing wea

t for one installation, consisting of one station outfit of 1 -in gongs, with a similar engine room outfit so that engineer can return signal, 1 extra bell at shaft mouth, and 200 ft of double-braid rubber-covered No 16 conductor wire, cost $35. Besides this, 150 ft of 0.75-in pipe was used for conduit, the shaft being very wet; also a few insulators on the surface. Labor cost of installation, about $17. The 3 gongs and 2 magnetos were connected in series.

C. Power or lighting circuits (direct current) not exceeding 220 volts, where

cages. Plain steel colliery cages, for a gross load of 4 000 lb; for heavier loads, up to 6 000 lb. A combined anthracite district, weighs 5 600 lb, has a deck 6 ft by 500-lb car and 6 000 lb of coal. Cage at Sugar Notch s 5 000 lb, car 2 500 lb, and contents 6 500 lb. Drop- weighs 2 680 lb, car 1 270 lb, contents 2 000 lb. Large ges weigh 6 000 to 8 000 lb. Single-deck cages, with n gross load, weigh 900 to 1 400 lb; for 3 000-lb load, eavier loads, up to 2 800 or 3 000 lb. Each additional the weight. Self-dumping cages are 30 to 40% heavier cages of standard design cost 8 to 12¢ per lb; heavy e from special designs requiring new patterns, cost is

24. Design of Cages

ould be 10, whence allowable unit stresses for iron and lb; and for compression, $S = 6\,000 - 70\,(l \div r)$; where nd r least radius of gyration, both in inches. Rivets 5 000 lb; double shear, 10 000 lb. Bolts, when used in pins, single shear, 3 500 lb, double shear, 7 000 lb. If car and contents, and the dimensions of hoisting com- esign is a matter of mechanics and knowledge of the l auxiliary parts, as determined by practice. Clearance eck and shaft timbers is 2 to 4 in. Width is fixed by tance between guides, less thickness of shoes and side between shoes and guides (Art 23).

nsions of cage deck, and place crosspieces equidistant. Small ading the ends; long decks may have 5 to 7 crossbars. Max- l its point of application on the deck rail are determined, and nbers are then calculated as beams (Sec 43). It is to be noted dy is not placed symmetrically on its truck; one pair of wheels r. Throughout the calculations the dead load is multiplied l (Art 8). If l = length of rail between crossbars, and W = ment $M = 0.25\,Wl$; also, $M = \phi S$, where ϕ = unit stress = ctural shape is used, $S = 0.25\,Wl \div 6\,000$, and proper size is . For a rectangular bar, $M = \phi bd^2 \div 6$; in which b is width ssume b and solve for d, in $d^2 = (3\,Wl) \div (2 \times 6\,000\,b)$.

DECK CROSSBARS is determined by relation between their dis- of car, remembering that front wheels may carry more load

STANFORD LIBRARIES

in which, P = load on each spring; S = max unit stress = 80 000 lb; R = r
center of coil; l = developed length of coil; G = modulus of elasticity in te
12 000 000; d = diam of spring rod; f = deflection of spring in inches under
In this case, pull from drawbar to chain wheel or lever must be converted into co
load in direction of axis of the spring. (See also Sec 41, Art 10.)

25. Caging Devices and Landing Chairs

Caging of small cars is nearly always done by hand. Large cars a
often caged by hand; but mechanical devices are common, especially in co

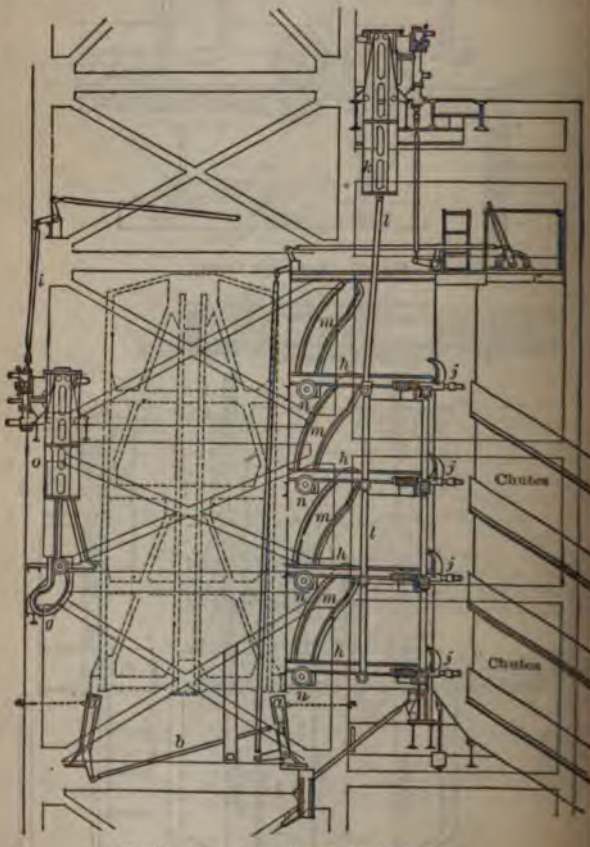

Fig 107. Surface Landing, St Michael Colliery

and increase capacity and safety. For hand caging, where station layou
mits tracks on both sides of shaft, the track approach to cage is laid with
2% grade, so that cars will run on by gravity, the loaded car pushing

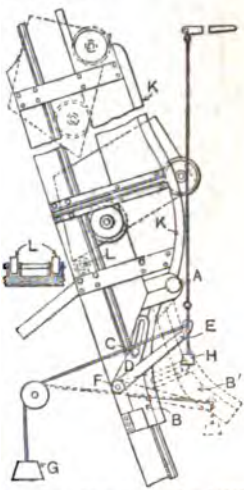

Fig 122. Skip Dump for Intermittent Service (*E & M J*)

e skip body, which is piv- d guide frame, is thrown a dumping angle by a pair of small wheels, near upper ich run into a curved slot-like track attached to head- nt.

STANFORD LIBRARIES

Fig 123 shows dumping track for the skip in Fig 120. Skip body rests on shafts bolted to guide frame, and far enough apart to insure stability of skip w hoisted (Fig 118 and 119). One shaft passes through 2 heavy pillow blocks bolted to skip body, thus forming a pivot on which the body rotates. The o rests in pillow blocks without caps, also bolted to the skip bottom. Track designed that skip body will not reverse, and go down head first when low Kimberly skip (Fig 118), this is prevented by the long links *L*, in which slide t thus limiting the angle through which swing outward. More common devic of roller wheels attached to side plates ing track (Fig 123) in such position horns (Fig 119, 120) projecting forw front end of skip body will just slide o these rollers thus carry weight of s dumping wheels are being lifted acro reversed portion of dumping track, an trip they insure that skip body will right side up. Instead of 2 rollers, a c bar or roller spanning gage of track is s used, but is liable to interfere with fr ing of ore. When dumping wheels are (Fig 119) they should be placed close ing side of skip, so that ends of pivot will have clearance space between the main and dumpin The farther this shaft is from center line of skip, the less th to accidental overturning, but the greater is the force re dump skip, thus throwing excessive stresses on guides. M are subjected to heavy side thrust at dumping point, a be well reinforced and bolted to headframe. Pivoting sh ally placed at 0.33 to 0.5 the distance from center line body, 0.375 being good practice. For small skips the s are ¼ to 5/16 in; front plate, ⅜ in; bottom plate, 5/8 to ½ large skips, the sides are ½ in, and the front and bottom 5/ in some of the Mich copper mines, even heavier.

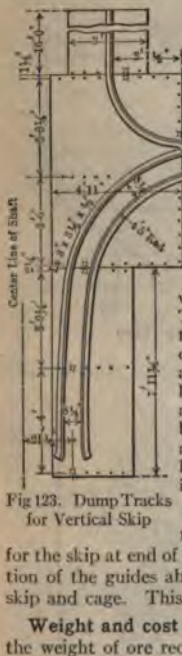

Fig 123. Dump Tracks for Vertical Skip

Handling men in vertical-skip shafts. F numbers of men, a double or triple-deck cage is sub for the skip at end of shift. The change may be made quickly by hingi tion of the guides above shaft collar, and providing a small crane for skip and cage. This method is practiced at Butte, Mont, and elsewhe

Weight and cost of skips. The weight of inclined-shaft skips is ab the weight of ore reckoned at 110 to 120 lb per cu ft. Cost is from 5 per lb at factory. For standard vertical skips Allis-Chalmers Mfg following weights, including dumping guides or cradles:

Table 34. Standard Vertical Skips (Allis-Chalmers Mfg Co)

Capacity, cu ft	Wt, without safeties, lb	Wt, with safeties, lb	Capacity, cu ft	Wt, without safeties, lb	Wt, safet
20	2 200	2 300	70	3 600	4
30	2 400	2 600	80	3 900	4
40	2 550	3 050	90	4 300	5
50	2 900	3 500	100	4 700	5
60	3 250	3 950	.....	.....	.....

Dumping cradles for 20 to 60-cu ft skips weigh 2 500 lbs; for 70 to 1 skips, 4 000 lb. For the 8 and 10-ton skips used in some deep mines, the are greatly in excess of above figures. Vertical skips with safety cate 7 to 8¢ per lb.

27. Overwinding

en for any reason the hoisting engineer fails to check
e to rest at surface landing. In such case, the cage
the sheave and its supporting timbers at top of head-
ne should be sufficient to allow reasonable clearance

vation, this fact wou ally be the determini in design. For deep excavated in ore or gate or chute and it should be carefully since it may be sub unusual loads due to ing above and then fal some height.

29. Ore Bin

Types. For ore, stone and coal, bins signed: (*a*) of rectan tion, with flat bottom hopper bottom, either inverted pyramid or wedge-shaped; (*c*) of circul with flat, conical or hemispherical bottom; (*d*) as a suspension bunk FLAT BOTTOM BINS are built entirely of timber, steel frame with timber all steel, or reinforced concrete. They are best suited to conditions material is discharged at center, or at various points, of the bottom, veyers or into cars. Advantages: larger storage capacity for the same f occupied; simplicity of construction; the ore forms its own bottom and wear on the floor, except around the discharge spouts. Disadvantag can not be completely emptied without shoveling the material lying angle of repose. HOPPER-BOTTOM BINS are built of timber, steel, or concrete. If of timber, the sloping sides of hopper portion should be steel plate. If bottom is pyramidal, the bin can be discharged complete the vertical cross-section is triangular or wedge-shaped, there will always of ore between chutes which will not run out. Pyramidal bottoms are for discharging the material from a point underneath the bin; wedge-sh toms, for discharging at one side. If discharge on each side is desired, bo inverted V (Fig 138). CYLINDRICAL BINS are of steel or reinforced concr vantage: economy of material for a given capacity, because the walls are only and but little framework is necessary except for the substructure. are no bending stresses in the walls, these bins can be made much de securing a larger capacity on same ground space, with same or a less q structural material. Their bottoms may be flat, hemispherical or conic PENSION BUNKERS are of steel plate or reinforced concrete. The bi

, which in turn are supported by columns. Weight assume form of the equilibrium polygon (Sec 36), es in plates are tension only. As form of the curve es of loading, the plates are slightly distorted; and einforcing, or steel framework supporting the rein- the concrete serving only to protect the steel.

loaded the stress in the plates is 17 000 lb per lineal ft. Openings are provided in th just above discharge spouts, so that the mater al can be loosened up if it should b

Cost of timber bins. Labor, nails, bolts, and iron work, exclusive plate lining, cost $20 to $25 per 1 000 bd ft, to which is added the timb

Cost of concrete bins. Four bins of the Croton iron mines (Exam cost, after crediting the future value of the form lumber:

For foundations, 221 cu yd at $3.81	$ 842
Structure above foundations, 380 cu yd at $9.76	3 720
Total	$4 562

This includes labor and material, lumber and reinforcement, but not the cost of tion, nor charges for superintendence and depreciation of plant.

A 400-ton reinforced-concrete coal pocket, at the Atlantic City (N J) water 30 ft diam, with conical bottom and pyramidal roof. Concrete was 1 cement, 2 5 gravel. Plain reinforcing bars were used. Excavation, 233 cu yd; concrete, 31 steel for reinforcing, 13 700 lb; steel beams, plates, etc, 3 250 lb. Contract price

A group of 4 reinforced concrete bins for sand storage, with a total capacity of yd, required 680 cu yd of concrete and 4 510 lb of steel reinforcing. Labor, 80 days for 11 carpenters and 14 laborers.

Cost of steel bins comprises: (*a*) cost of material; (*b*) cost of fabri (*c*) cost of erection; (*d*) cost of transportation. Cost varies with local tions, and largely with the design. As a guide for preliminary estimat following figures in ¢ per lb may be used:

(*a*) Material	1.8
(*b*) Fabrication, including drafting, mill details and shop labor, painting, and transportation from mill to shop	2.1
(*c*) Erection	1.0
Total cost, exclusive of freight from shop to point of erection	4 9¢

According to M. S. Ketchum (43) the costs of bins of different materials and d as follows: Wooden bins cost about half as much as steel or concrete. Ste

her types, costing 50 to 70% as much as rectangular bins. cheaper than rectangular. Reinforced-concrete bins cost steel bins of same type.

m receiving bins (Fig 146), at the smeltery of the n, Ariz, is given in Table 36 (46).

36. Cost of Steel, V-Bottom Bins

abor	Material	Total	Quantity	Total unit cost
23.11	$ 39.16	$2 342.27	1 428 cu yd	$1.64

walls depend upon the weight per unit of volume, ure content of the bin filling, and the angle of friction alls.

the walls are flat, and the plane of rupture cuts the ts, the theory and formulas for retaining walls apply. heory, the plane of rupture forms with the bin wall a st," which exerts pressure on the wall. For a vertical r heaping of the material above the top, the plane of between the wall and the plane of repose of the filling, ust is normal to the wall. In this case, the resultant s making an angle with a normal to the wall equal to en the filling and the bin wall. Rankine's theory, on hat the direction of the resultant thrust on a vertical e top surface of the filling; also, that the angle between tant thrust and a normal to the wall is never greater the bin filling. In both methods of solution the point tant stress is assumed at one third the height of wall,

STANFORD LIBRARIES

Algebraic methods. Factors in the formulas for pressure

P = resultant pressure per ft of length of wall
N = total normal pressure per ft of length of wall
ϕ = angle of repose of bin filling
ϕ' = angle of friction of the filling on the wall
θ = angle between plane of wall and the horizontal measu
δ = angle of surcharge
ε = angle between direction of P and a normal to wall
λ = angle between P and the horizontal
h = vertical height of wall
w = wt of bin contents per cu ft

Rankine's formula, for a vertical wall without surcharge, is

$$P = \frac{1}{2} wh^2 \frac{1 - \sin\phi}{1 + \sin\phi}$$

and for a vertical wall with surcharge δ:

$$P = \frac{1}{2} wh^2 \cos\delta \frac{\cos\delta - \sqrt{\cos^2\delta - \cos^2\phi}}{\cos\delta + \sqrt{\cos^2\delta - \cos^2\phi}}$$

If $\delta = \phi$, then $$P = \frac{1}{2} wh^2 \cos\delta$$

In Eq 40, 41, and 42, the direction of P is assumed parallel to upp
contents, and its point of application at one-third of the vertical hei

Coulomb's theory gives the following formulas:

$$P = \frac{1}{2} wh^2 \frac{\sin^2(\theta - \phi)}{\sin^2\theta \sin(\theta + \varepsilon)\left(1 + \sqrt{\frac{\sin(\varepsilon + \phi)\sin(}{\sin(\theta + \varepsilon)\sin(}\right.}$$

If, in Eq 43, ε be made equal to zero, $P = N$ and

$$N = \frac{1}{2} wh^2 \frac{\sin^2(\theta - \phi)}{\sin^3\theta \left(1 + \sqrt{\frac{\sin\phi \cdot \sin(\phi - \delta)}{\sin\theta \cdot \sin(\theta - \delta)}}\right)^2}$$

For a vertical wall $\theta = 90°$, and Eq 44 reduces to

$$N = \frac{1}{2} wh^2 \frac{\cos^2\phi}{\left(1 + \sqrt{\frac{\sin\phi \cdot \sin(\phi - \delta)}{\cos\delta}}\right)^2}$$

For a level top surface $\delta = 0°$, and Eq 45 reduces to

$$N = \frac{1}{2} wh^2 \frac{1 - \sin\phi}{1 + \sin\phi}$$

which is identical with Rankine's formula (Eq 40) for a vertical wa
of filling material level with the top.

Cain's formulas assume that $\varepsilon = \phi'$, Eq 47 to 61 applying also
addition to previous nomenclature, N' = normal pressure on the wa

(*a*) Vertical wall, surface of filling level, $\varepsilon = \phi'$,

$$P = \frac{1}{2} wh^2 \frac{\cos^2\phi}{\cos\phi'\left(1 + \sqrt{\frac{\sin(\phi + \phi')\sin\phi}{\cos\phi'}}\right)^2}$$

$$N = P\cos\phi'$$

If $\phi = \phi'$, $$P = \frac{1}{2} wh^2 \frac{\cos\phi}{(1 + \sin\phi\sqrt{2})^2}$$

If $\phi' = 0$, $$N' = \frac{1}{2} wh^2 \tan^2\left(45° - \frac{\phi}{2}\right)$$

$= \delta$, $s = \phi'$,

$$\frac{\cos^2\phi}{\cos\phi'\left(1+\sqrt{\frac{\sin(\phi+\phi')\sin(\phi-\delta)}{\cos\phi'\cdot\cos\delta}}\right)^2} \tag{51}$$

$$\delta = \phi, \quad P = \frac{1}{2}wh^2\frac{\cos^2\phi}{\cos\phi} \tag{52}$$

$$N = P\cos\phi' = \frac{1}{2}wh^2\cos^2\phi \tag{53}$$

$$\phi = 0, \quad N = \frac{1}{2}wh^2\cos^2\phi \tag{54}$$

$< 90° + \phi'$, $\delta = 0$,

$$\frac{\sin^2(\theta-\phi)}{\sin(\phi'+\theta)\sin^2\theta\left(1+\sqrt{\frac{\sin(\phi+\phi')\sin\phi}{\sin(\phi'+\theta)\sin\theta}}\right)^2} \tag{55}$$

$$N = P\cos\phi' \tag{56}$$

$< 90° + \phi'$, surface surcharged,

$$\frac{\sin^2(\theta-\phi)}{\sin(\phi'+\theta)\sin^2\theta\left(1+\sqrt{\frac{\sin(\phi+\phi')\sin(\phi-\delta)}{\sin(\phi'+\theta)\sin(\theta-\delta)}}\right)^2} \tag{57}$$

$$N = P\cos\phi' \tag{58}$$

$> 90° + \phi'$, $\delta = 0$,

$$\frac{1}{2}wh^2\sqrt{\tan^2\theta+\tan^4\left(45°-\frac{\phi}{2}\right)} \tag{59}$$

$$N = P\cos\phi' \tag{60}$$

nponent of P parallel to wall, the thrust in plane of wall is

$$T = P\sin\phi' \tag{61}$$

eding formulas for shallow bins do not apply when a e of rupture of contents cuts the bin walls. Following Ketchum (43):

$$V = \frac{wR}{k\mu'}\left(1-e^{-\frac{k\mu' h}{R}}\right) \tag{62}$$

$$L = \frac{wR}{\mu'}\left(1-e^{-\frac{k\mu' h}{R}}\right) \tag{63}$$

Suspension bunkers. The stresses are due to a load which varies from at the support to a maximum at the center, and the loading varies nearly ordinates to a straight line (Fig 147).

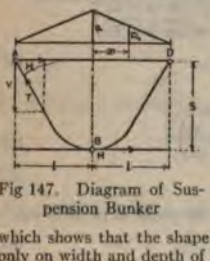

Fig 147. Diagram of Suspension Bunker

P = maximum load at center of bin, lb
l = one-half bin span, ft
S = depth of bin, ft
w = wt per cu ft of bin filling
T = maximum tension in plate per ft of length
C = capacity of bunker in cu ft per lineal ft of
B = lowest point of bin and origin of coordinat

The equation of the curve of the bunker is.

$$y = \frac{1}{2}\,\frac{S}{P}\left(3x^2 - \frac{x^3}{l}\right)$$

which shows that the shape of the curve is independent of maximum load and de only on width and depth of bin.

Capacity of a bunker level full is $C = \frac{3}{4}\,lS$

Maximum pressure P at center is calculated as follows:

$Pl = Cw$, $P = Cw \div l$, and from Eq 65 for a bunker level full, $P = \frac{3}{4}\,Sw$

Tension in the plates at supports A and D is

$$T = Cw\sqrt{\frac{1}{4} + \frac{P^2}{9\,S^2}}$$

Length of bin curve is not exactly determinate. If L be the length for one-half the

$$L = \int_0^l \sqrt{dx^2 + dy^2}$$

By substituting values of dx and dy from Eq 63, the length of one-half the curv

$$L = \frac{1}{2\,P}\int_0^l \sqrt{4\,P^2 + 9\,S^2\,(2\,xl - x^2)^2}\,dx$$

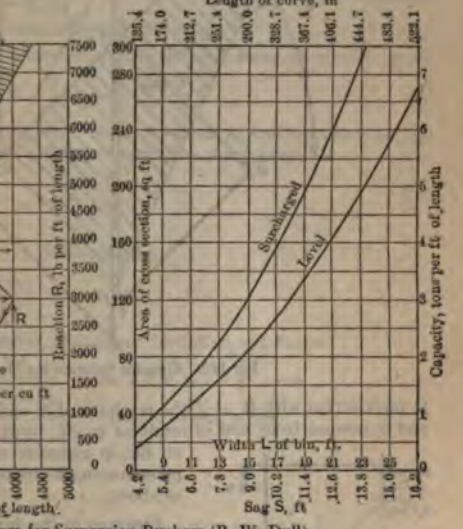
By using Simpson's rule for approximate integration, with 10 divisions, one-half length of curve becomes

$$L = \frac{1}{2\,P} \times \frac{l}{30}\,[y_0 + y_{10} + 4\,(y_1 + y_3 + y_5 + y_7 + y_9) + 2\,(y_2 + y_4 + y_6 + y_8)]$$

$$= \sqrt{4P + 9S^2(2xl - x^2)} \qquad (70)$$

= 0; y_1 = value of Eq 70 for $x = l \div 10$; y_2 = value of on. Ten divisions give sufficiently accurate results for

for calculating stresses, capacity, and length of curve of Fig 148. It is for coal weighing 50 lb per cu ft. For ltiply the stresses in the diagram, and the capacity per eight of material per cu ft to 50 lb. To use the diagram, of coal per ft of length is required, and that the bin is to am at 5 tons on the right and pass to the curve for sur- d the corresponding depth, 14.55 ft, and width, 19.25 ft, 72.2 in. Passing on to the left, the reaction R is 5 000 lb, o lb with the diagonal line is the compression B, 2 900 lb, s T in plate = 5 800 lb.



am for Suspension Bunkers (R. W. Dull)

allow bins a combination of algebraic and graphic solution. In bin $ABCD$ (Fig 149), with smooth e normal pressure on side BC is $N = \frac{1}{2} wh^2 \frac{1 - \sin \phi}{1 + \sin \phi}$.

N, unit pressure at $B = 0$, and the unit pressure tal normal pressure N_2 and unit pressures on side or the bottom DC, continue AB and DC to inter- riangle EBC acts through its center of gravity, and ressure on $EC = cb$, represented by the area of the mal pressure Co at C = (area ECo) ÷ ½ EC. Unit ound by construction, and the total normal pressure is represented by area of trapezoid $DCon$. It acts gravity of the trapezoid. The component of the g parallel to the plane of DC is de. If, in Fig 149,

STANFORD LIBRARIES

the bin be extended, with a horiz bottom, to the right, to such dist
the plane of rupture laid off from C to right of BC (instead of to left,

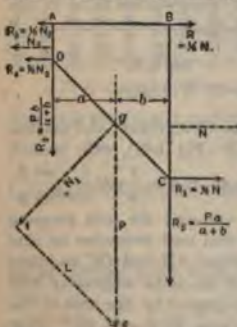

Fig 150. Stresses in Bin Framing

Stresses in the bin framing. Total
vertical stresses at the intersections are
Fig 150. These are carried by the frames
calculated in the ordinary manner.

Trautwine's formulas for the pressure on v
walls are:

(*a*) Surface horizontal, horizontal pressure
length of bin is $\frac{1}{2} wh^2 \tan^2\left(45 - \frac{\phi}{2}\right)$

For anthracite coal, total horizontal press
and pressure on lowest foot = 9.78 (z h

For bituminous coal, total horizontal press
and pressure on lowest foot = 6.32 (z h

(*b*) Surface sloping, $\delta = \phi$

Horizontal pressure $= wh^2 \sin^2\left(45 - \frac{\phi}{2}\right)$

al horizontal pressure = 14.22 h^2 and pressure on lowest foot

otal horizontal pressure = 10 h^2 and pressure on lowest foot

are usually calculated the same as for deep bins. For horiz
Eq 63 applies. Tensile stress in walls per ft of height at any
oriz press, lb per sq ft (Eq 63), and r = radius of bin. If
will be carried by bottom. If deep, Eq 62 applies. For
and equal at all points. If conical, tensile stress, at any
o an element of cone, is

$$H = \frac{\operatorname{cosec} \theta}{2\pi r_1} (\pi r_1^2 V + W_1) \qquad (73)$$

s with horiz; r_1 = radius of cone at point considered; W_1 =
this point; V = Eq 62, considering radius of bin r_1 instead

conical bottom is $H_1 = Lr_1$ (74)

3, using r_1 for r. In spherical bottoms, the tension parallel

$$H_2 = \frac{1}{2} Vr' + \frac{W_1 \operatorname{cosec} \theta}{2\pi r_1} \qquad (75)$$

in Eq 73, θ = angle of tangent to meridian with horiz, and
ension normal to a meridian at any point is

$$H_3 = \frac{1}{2} Vr' \qquad (76)$$

D CONTROL OF MINE WATER

Sources of Mine Water

h outcrops is the chief source of mine water in coun-
ze rainfall, especially where mines are worked to the
drainage areas are above or tributary to extensive
ch cases, mines may be subject to sudden floods, de-
d usually requiring definite times to reach the work-
quantity and character of precipitation, and time and
inflow, should be kept for their value in giving warn-
ng under water-bearing surface wash, as in alluvial
to similar flooding, are subject to continuous perco-
, the amount dependent upon the character of the
mine workings to buried outcrop. In case of a coal
bed of fire-clay, the latter may be washed out over
isastrous inflow. Surface flood water may also find its
r open crop-falls,

STANFORD LIBRARIES

Surface water through cracked or broken measures is perh dangerous and troublesome than that from open outcrops. Where has been extensively worked by open or by shrinkage stopes unde rock cover, the network of cracks and crevices may admit large qu both surface and ground water, combining serious permanent flow wit cal flooding from rainfall.

Flooding may also come from caves extending into water-bearing wash or wa depositions, from mining under too thin a rock cover, or cutting into "pot buried valleys. In 1885, at Nanticoke, Penn, 26 men were buried in quicksa pot-hole over 100 feet deeper than the surrounding rock.

Water from permeable measures is always possible, and in formation massive sandstones may be expected. It may enter as seepage, or under pres from large areas, resulting in persistent inflows. Relief can be obtained only ing entire basins, or by general lowering of ground-water level. WATER FROM OR UNDERGROUND CHANNELS is sometimes encountered in shaft sinking or in mi coming in unexpectedly and in large volume. It may persist to the complet of territory tapped. WATER FROM UNSUSPECTED UNDERGROUND CAVITIES, eith caves or abandoned mine workings, is fortunately rare. Its serious aspect, quantity of water, is suddenness of inflow, which may endanger life and qu lower workings.

2. Prevention of Inflow

Surface. It is generally cheaper to keep water out of mines than to after it has entered. While it may be impossible to prevent the entr water the amount can usually be materially decreased by attention to inflow. In impervious soil, entrance of surface water can be minimize planned ditching around outcrop or fractured areas. In permeable so should be lined, or wooden or concrete flumes installed. If streams or channels cross outcrops or fractured areas they should be flumed, or di canals, designed to take maximum flood volumes, and located to minim of rupture from surface settlement often occurring during flood period

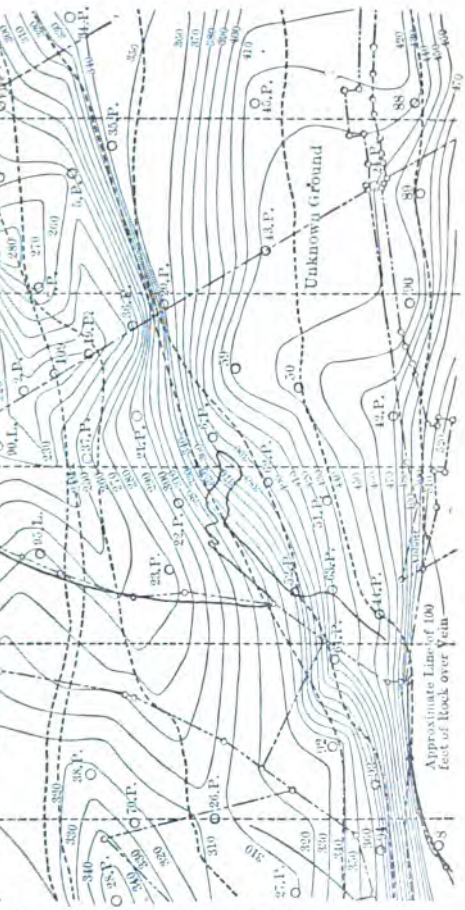
Drainage works are sometimes built through extensive districts by a comb interests, as in Hazleton region, Penn, where Black Creek has been diverted the coal measures for miles, relieving the drainage situation in a number o each of which formerly pumped practically the entire creek flow.

Besides diverting surface water, provision must be made for delivering th of mine pumps outside of drainage area of mine. This may cause contam streams. Some state courts have ruled that discharge of mine water into drainage channels is permissible, but that damages may be recovered for in into streams not reached by gravity in case the mine should fill. Thus draina discharging onto unpolluted watersheds may furnish ground for damages.

Entrance of flood water through mine openings other than crop-falls or cracke should be impossible. If there are openings below flood level, along creeks or flood plains, shut-off doors or temporary dams should be installed. In pla openings flood records should be obtained, and openings placed well above d Damage from flooding may be so serious as to warrant considerable expenditu it. In case of shafts, the cost of extending waterproof curbs above possible fl small, and the shaft spoil may be economically used for filling necessary to above high-water mark. This has been done at many shafts in the flood plain hanna River, Penn, recent shaft curbs being at least 5 ft above highest rec mark; besides which, provision is made for shutting openings promptly possible higher floods.

Underground. In mining under heavy water-bearing wash or q it is imperative to leave sufficient rock cover, and to keep workings l below buried outcrops to avoid danger. Preliminary exploration of face should be done by borings sufficiently close together for makin reliable contour map of the buried rock surface.

area of the buried valley of Susquehanna River, showing the urface revealed by borings. The wash varies from less than nd without borings the workings might easily have been ex- ep recesses in the rock. In such boring, especially in strati- oles must be continued into the rock, to determine its nature.



Map of Rock Surface of Buried Valley

be grouted to the rock surface, to prevent entrance of water t mine workings.

uired between workings and overlying wash de- acter of deposit, nature of overlying rock and method **al rule is possible.** In the Wyoming Anthracite Field,

STANFORD LIBRARIES

Penn, under the Susquehanna Valley and under the river itsel
left varies from 100 to 50 ft minimum; under deeper wash,
of thickness of wash. Under average conditions, with sands
overlying mine openings, and with ample pillars, a rock thick
ings equal to ½ of total cover is considered a reasonable minim
pitching measures, thickness of cover is determined by the dista
required to prevent inflow along bedding planes; best deter
test openings toward outcrop.

Douglas Bunting gives the following relations for 24 ft width of mi

$T = 1.5\sqrt{d} + 5$ (strong measures, rock surface fully explored).

$T = 1.5\sqrt{d} + 15$ (softer measures, liable to disintegration, rock surf

$T = 1.5\sqrt{d} + 40$ (strong measures, rock surface imperfectly explo

$T = 1.5\sqrt{d} + 50$ (softer measures, liable to disintegration, rock explored).

In these formulas: T = thickness of rock cover, d = depth of surf

Grouting and waterproof linings. Inflow from water- avoidable by waterproof linings of shafts and other opening under pressure into surrounding rocks.

In approaching known or possible OLD WORKINGS, and whe stone where cavities may be expected, drill holes, preferably b valves previously secured, should be kept well in advance o avoid disastrous inrushes of water, and to control flow from may be tapped by holes, letting the water out only in such such times as may be suitable for capacity of the pumps.

No means have yet been devised for materially diminishing the inf water, as encountered in porous formations of some western mines. ing plant is the sole safeguard. Grouting in advance of sinking ma bore holes surrounding proposed shaft location; or during sinking drill holes; or subsequently behind shaft lining of steel, brick, stone

In case of fissured or broken ground the flow may be reduced and cut off by cement grouting under pressure through bore holes, or by t process (23), consisting of injection through drill holes or into partl chopped straw, sawdust or other finely-divided material, followed by (first used at the Flat River, Mo, mines of Federal Lead Co, where it the flow from a network of fissures previously unconquerable).

Sometimes, when water pressure in cracks or fissures is so great th aration for grouting or mudding only results in spreading the water t areas of fractured or permeable rock, the pressure may be relieved holes up into the cracks, and plugging and grouting cracks, after w which have taken the flow temporarily are permanently closed.

Tapping underground reservoirs. When approaching of water under pressure, bore holes should be kept in advanc bored in such manner as to permit withdrawal of drill rods a when water is encountered. One hole (better 2 holes) should ahead of face, 10 to 20 ft in hard rock, 75 to 100 ft in soft r coal. Other holes, of about same depth, should be drilled (about 30° from center line) at intervals of 8 to 12 ft. If unexpectedly, insert a dry soft-wood plug of diameter smal freely; push to bottom of hole, and hold there by a rod o length, and a larger plug driven into neck of hole. In seve plug will have swollen tight, when outer plug can be remo outer 5 or 6 ft of hole. To a piece of heavy pipe screw a one end and a straight-way gate valve at other. Insert cou larged hole, and wedge with oakum and dry soft-wood wedge

$G = 1040\sqrt{\frac{d^5 h}{l}}$, in which: G = flow in gal per hr; d = diam pi

tive head, ft; l = total length, ft. In Fig 2, $b = h$.

The grade of pipe should be uniform, to avoid accumulations of ai To fill the siphon, for starting it, a short stand-pipe is placed at summ each end of main pipe.

Size of sump is chiefly dependent upon quantity of inflow. It enough to take care of inflow while pumps are stopped for ordin sump capacity of 8 hr maximum inflow, without submerging th ment, may be considered a minimum; capacities of 24 hr or more The possible results of deficient capacity are noted by W. F. Stau Tombstone mine, Ariz, was flooded, owing to a reduction of steam only 2.75 hr, involving large cost for recovery of the workings.

Proper location of sumps should be carefully considered in workings. Since haulage ways, with their drains, gravitate tow main sump is usually placed near foot of shaft or slope. W permit, a good sump is obtained at low cost by working out an ar to the dip, adjacent to shaft station, leaving ample chain p sump from lower workings.

Horizontal area of sump should be large. This gives large c material change in suction height of pump. Depth is of second Large sump area is also advantageous for condensing pumps, charge of heated water from condenser at a distance from su allowing it to cool before reaching pumps. In pitching, stratifi coal, where several veins are worked, the sump may sometim main workings and pumping plant in an overlying or underlyi being connected on main level only by a tunnel closed by a dar pipe from dam to pump is supplied with shut-off valves, thus, i mitting main workings to be flooded to considerable depths wit with operation of pumping plant.

Examples: At the Hazleton colliery, Lehigh Valley Coal Co, the Wharton vein, underlying main workings in the Mammoth. The Wh

third over that of a beam supported at both ends. The New York Buildin 1903 permit for concrete floors a bending moment at the support of $wl \div 20$, f on 4 sides, in comparison with $wl \div 12$, for support at ends only (w = total formly distributed, and l = length span in ft). Hence, it is safe to calculate dam as a beam having its shortest length, loaded uniformly and supported at using the formula:

$$s = \frac{wl}{2\,bd^2} \quad \text{whence,} \quad d = \sqrt{\frac{wl}{2\,bs}}$$

Fig 5. Stepped Abutment, Concrete Dam

in which: s = unit stress in extreme fibers; b = lin d = depth, in; w = total load, lb; l = length, in. I the strength of plain concrete in tension should be tak over 50 lb per sq in, whence for a dam with minimu 7 ft, built to withstand 500 ft head,

$$w = \frac{62.428 \times 500 \times 7}{12} = 18\,208 \text{ lb per linea}$$

$$d = \sqrt{\frac{18\,208 \times 84}{2 \times 50}} = 125 \text{ in}$$

Result: a dam 10 ft 5 in thick.

A saving in material can be made by building a flat dam of reinforced concr

If the rock formation be of doubtful strength to stand direct thrust of either flat dam, a larger surface of abutment may be obtained by stepping the notches (Fig 5). In a large Schuylkill County, Penn, colliery, a special method was employed (Fig 6) to drown out a fire in upper levels without complete flooding. As the pillars were not considered safe to support the pressure which would be brought on the lower dams, these were relieved by flooding behind auxiliary dams, thus building up a series of counterbalanced pressures. Hence the coal in each pillar took no more pressure than that due to a sing any one dam.

Fig 6. Series of Dams, with Counterbalanced Pr

5. Drainage Tunnels

These are advantageous where location and topography permit. first cost is large, the elimination of pumping charges and freedom fro bility of flooding the mine, due either to accident to pumps or powe or to labor troubles, may warrant the investment. In most cases, h ditions are such that only the upper levels of a mine can thus be unwa gravity. When workings extend below tunnel level, pumps must be i But, drainage tunnels still have the advantage of saving cost of ra entire volume of water through a height equal to distance below w which tunnel intersects deposit. An estimate of length of tunnel fo comparison with a pumping plant must be made with careful consider cost of driving, maximum quantity of water possible for short peri height of lift for which the pumps and power plant must be designed.

Cost of drainage tunnels depends chiefly on character of rock, rate and cost of power and supplies. It ranges from about $5.50 to $16.0 yd; average say $10.00. Costs per linear ft of a number of western range from $13.50 to $27.25, averaging about $22.00. Cross-sectional

more large, single-acting plunger pumps, located in the long wooden or steel rods to steam engine on surface. engines were always used, but are now practically obsotype, a few of which are still in operation in the anthram cylinder is set at mouth of shaft, directly in line with inder is usually single-acting, the steam raising rod and weight on down stroke and are cushioned at end of stroke heavy rod, which is counterbalanced by one or more greased guides or is guided by rollers. Owing to the on, the speed is necessarily slow, partly compensated by Pumps with 24-in plungers and 10-ft stroke, with steam were not unusual; speed, 3 to 5 double strokes per min.

moderately economical of steam. A reported test (3) shows Assuming 10% friction, this shows a duty of 36,000,000 ft-lb team cylinder was 44 in diam by n-condensing; 21 5-in plunger, lift tor cards from this test. Working uld do considerably better. Cost large Cornish installation on the 3 per i h p per month; capacity 152 ft head. The question of econnts is largely one of type of driving gines, with their rather complicated omical, when working under proper as often been the case in the U S, y ordinary high-pressure engines eir advantage. Cornish pumps, though very costly to install. ely free from danger of flooding, as the pumping parts only are ell under water as out, provided valves remain unobstructed.

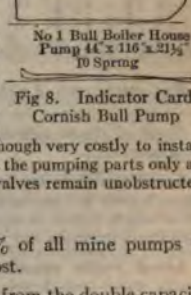

Fig 8. Indicator Cards, Cornish Bull Pump

9. Direct-acting Pumps

s probably comprise over 80% of all mine pumps in ges being simplicity and low cost.

Single and duplex. Aside from the double capacity of the duplex, there is little choice between these forms. Though desirable in point of compactness and moderate cost, their duty is low, because, having no flywheel, and their moving parts coming to rest at the end of each stroke, steam can not be used expansively. This

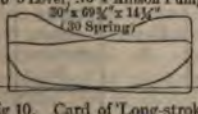

Fig 10. Card of Long-stroke Single-cylinder Pump

umption. Tests of 39 pumps (7) gave an average p per hr, ranging from 49.7 lb for a large, long-stroke

STANFORD LIBRARIES

single-cylinder pump, to 103.7 lb for a very short-stroke duplex pump, i condition.

Fig 9 is a typical indicator card from a short-stroke duplex pump, showing clea irregularity in stroke characteristic of the type. Total steam consumption und was 58.9 lb per i h p per hr. Fig 10 is from a 30 by 69.75-in single-cylinder pump, in plunger. The card shows starting effort on water column, and the curve of the from the small ports into the large cylinder. This pump, working against a 326-f showed total steam consumption of 49.7 lb per i h p per hr. Its economy was mat increased by exhausting into tail pipe, at a little below atmospheric pressure.

Compound direct-acting pumps. The objections to simple, direct- pumps can be largely overcome by compounding the steam cylinders, expa from first into second, and to a third and fourth if desired, in triple and ruple expansion pumps. While permitting expansive use of steam, the stant thrust essential to the design is retained, with greatly reduced consumption. In flywheel engines the only advantage of compounding reducing cylinder condensation, since, having a flywheel to equalize pow livery, any desirable ratio of expansion is attainable in a single cylinder. theoretical saving due to compounding may be shown as follows: Ass high-pressure cylinder 1 sq ft net area by 1 ft stroke, with an interme cylinder 4 sq ft area, and a low-pressure cylinder 16 sq ft area; then, initial steam pressure of 164 lb absolute, and neglecting cylinder condens clearance, and frictional losses, the results would be:

Cyl	Contents, cu ft	For'd press, lb abs	Back press, lb abs		Mean effec press, lb abs		Total press,	
			Cyl 2	Cyl 3	Cyl 2	Cyl 3	Cyl 2	Cy
1	1	164	38	38	126	126	18 144	18
2	4	38	0	8	38	30	21 888	17
3	16	8	.....	0	.....	8	.....	18
							40 032	53
Equivalent area of a single cylinder, of same stroke.....							1.7 sq ft	2.28

Ratio of steam consumption for uniform power: single, 1; compound, 0.53; expansion, 0.44.

In practice there are necessary losses: in cylinder condensation, in friction of through ports and passages, and in friction of additional pistons and other moving all of which reduce theoretical saving. Furthermore, for efficient multiple expa high steam pressures and vacuums are essential.

Actual steam consumption of compound and of multi-expansion direct-a pumps varies considerably. A plant of triple-expansion pumps at Bisbee, Ari showed 80 000 000 ft-lb duty per 1 000 lb steam. Recent tests of compound pu made with steam meter, gave following results under best load conditions:

Steam cylinders, in	Plunger, in	Stroke, in	Head, ft	Initial steam pressure, lb	Remarks	Duty per 1 000 lb steam ft-lb
23 and 40	14	48	590	80	Condensing	69 000
26 " 45	14	48	590	80	"	65 000
30 " 50	14	48	757	70	"	66 000
17 " 26	10	36	269	75	Non-conds'g	39 600

nps, respectively 24 and 38 by 10 by 36 in and 25½ and der 675 and 668-ft lifts, and condensing into tail pipe with ctively 46 000 000 and 47 000 000 ft-lb duty (Fig 11).

of direct-acting pumps is shown tests of a 30 and 50 by 14 by pump, tested by steam meter. ion is due to a combination of low speeds, changes in friction l variations of steam pressure, tling to attain slow speeds.

No 4 Level, No 2 Jeanesville Pump 25½ & 38 x 36 x 10 9½ Revs.–30 Spring Siphon Condenser.

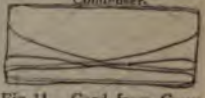

Fig 11. Card from Compound Pump

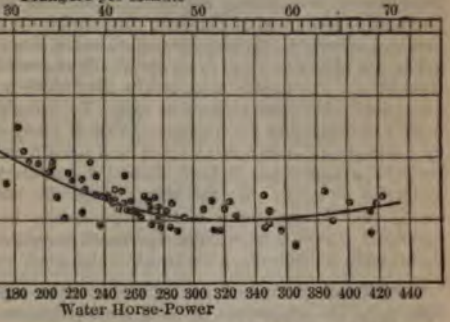
duty between similar pumps is steam pressure, and shows the e of designing pumps for much actually available. Many pumps are found by indicator initial pressure is half or even one third of the available. pressure found in 39 pumps (7) was 27.8 lb, boiler pressure minimum of 75 lb, during a 7-day test. This practice is



eed and Water h p, Based on 31 gal per Plunger. Example: Read to Bottom = 241 h p; then to Curve = 32.95 lb hp-hr; 241 × 32.95 = 8204.5 lb Steam per hr

le stoppage of pumps, in case of low steam pressure, but re cheaply provided for by ample reserve sump area, paid cessive expense for power. In wet mines, from 50 to 80% d for pumping, a saving in which is well worth extra expense plant, in order to permit installation of pumps properly

10. Flywheel Pumps

grade are common in waterworks and manufacturing are in mining. They range from quite small pumps st grade. Duties are from 100 000 000 to as high he best triple- and quadruple-expansion condensing mples may be cited two compound condensing fly- e plant (Art 9), 30 and 38-in steam, 6½-in plungers, lnst 1 000 ft head, which are said to have shown over The high-duty Knowles pumps, in Hazleton shaft of are reported to have given on test a duty of over pumps, of which there are a number in the West and

STANFORD LIBRARIES

Northwest, working under heavy heads, are among the best known of this of pump. At the Chapin mine, Iron Mountain, Mich, is a triplex differe Riedler, steam cylinder 22 and 36 by 30 in, differential plungers of 6¾ and 9 raising 2 200 gal per min, under 1 700 ft head.

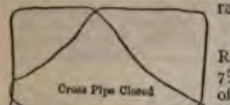


Fig 13. Card from Riedler Compound Pump

A comparison of indicator cards in Fig 13, from a Riedler cross-compound pumping engine, 13 and 20 7⅝ by 16-in cylinders, running non-condensing, with of Fig 10, from a larger direct-acting compound pump, at once the advantages attained by addition of a fly The disadvantages of the flywheel pump are: the gr weight and size of parts, higher cost, complication of anism, with resulting greater liability to accident or der ment, and the higher class of labor required to run succes high-duty pumping engines.

11. Electrically-driven Pumps

Plunger pumps have high efficiency, up to 85 to 90%, but, owing to disadvantage of requiring gearing to reduce the high speed of motor to necessarily slow speed of plungers, they are heavy, and expensive both in cost and in repairs. Where electric current is dear, their efficiency easily weighs the objections, and in all electrically operated plants their use shoul considered. The smaller sizes usually have single-acting plungers of the t type, dispensing with connecting rods. To maintain an even flow of wa from 3 to 6 plungers are common. A small pump of this type, 3¼-in plu by 5½-in stroke, driven at 33 r p m by a 100-h p motor, and delivering 25 per min against 1 000 ft head, showed a combined efficiency, for pump motor, of 78 to 84.4%; for pump alone the efficiency was from 86.5 90.9% (8). Large pumps of this type usually have double-acting, outs connected plungers, with large slow-speed motors and heavy gearing. T show excellent efficiency, quite equal to high-grade steam pumping engines.

Centrifugal pumps of the multi-stage type are coming largely into They have the advantages of compactness, lightness, relatively low first

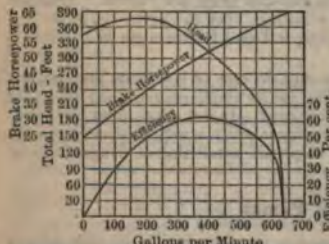

Fig 14. Curves from 5-inch Three-stage Centrifugal Pump at 1 788 r p m

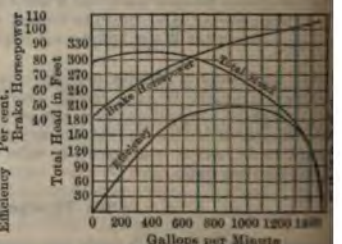

Fig 15. Curves from 8-inch Two-stag Centrifugal Pump, at 1 400 r p m

maintain a constant flow without shocks, and, owing to their high rotative sp are well adapted for direct connection to electric motors or steam turbi Their disadvantages are: relatively low efficiency and rather rapid wear, general unsuitability for gritty or very acid water. The efficiency of pu alone rarely exceeds 70% and falls rapidly as the pump departs in quantity head from its designed duty. Fig 14 and 15 (12) show the variation in effici

gals under different conditions. Fig 16 (13) exhibits lb steam, of a two-stage centrifugal, direct-connected rking against high ditions of variable to figure the com- mp at much over ler favorable con- r 70% combined d.

ompressed-air Driven Pumps

mpressed air is less efficient than by steam or electric- warranted: (*a*) in gassy collieries, where electricity is too far from boiler plant for economical steam trans- ere heat from steam pipes is objectionable, or heat would injure roof rock; (*c*) where there is no electric ent required would not warrant an installation. It is d air in pumps built for steam, and in cylinders not the pressure employed. Under these conditions it is of indicated power at compressor is represented by th reheated air, the efficiency may rise to about 30%. that ordinary direct-acting pumps fail to make full e volume is too great for compressed air operation. le from larger flywheel pumps, designed for the service. trouble from freezing in exhaust ports may be mini- rs and traps in air lines close to the pumps, and by of water, taken under column-pipe pressure, into the e valves.

igh efficiency, many extensive air pumping plants are in use. or explosion, and absence of exhaust steam and of heat from counterbalance the cost of extra power required. With and a steam consumption of about 25 lb per h-p hr, a total approximates a duty of 16 000 000 ft-lb per 1 000 lb steam idering the usual losses involved in carrying steam under- umping duty of about 20 000 000 ft-lb.

STANFORD LIBRARIES

13. Air-lift Pumps (see also Sec 15)

This system of pumping, while convenient, has low efficiency, exceeding 30% total and under unfavorable conditions falling to A submergence of air-supply pipe of about 55% of pumping l give best general results. The Pohlé air lift, usually considered a pumping only, was installed in the Candelaria mines, Chihua for lowering water in an extensive area of permeable rock, but placed by compound steam pumps. A test of a Pohlé pump gave following results (18):

Net lift above average water level	
Submergence of delivery pipe (air admitted to delivery pipe 5 ft above lower end)	
Diameter delivery pipe	
Diameter air pipe	
Volume water delivered per min	
Volume free air used per min, at 107 lb gage	
Consumption free air per cu ft water	
Horse power consumed by compressor	
Total efficiency	

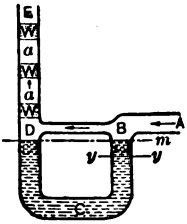

Fig 17. Diagrams of Starrett Air-lift Pump

Air-lift pumps have been applied for raisin in concentration of ores (20, 21), and for ha cyanide mills.

An ingenious air lift, not requiring subm in Fig 17 (22). Compressed air enters at *A*. U-pipe is raised by difference in pressure at due to throttling and friction, as air passes t diameter pipe *BD*. Thus the column *BC* is d and *CD* is correspondingly raised. The enteri cessive small volumes of water near *D* and e the ordinary air-lift pump. This pump (Starre through a considerable range of lifts by H. C to give from 25 to 34% total efficiency (inclu pressor), and from 36 to 50% for pump alon

14. Design of Mine Pumps (See also Sec

In general, piston pumps are the cheaper, but are unsuit about 300-ft lift is their limit in good practice. Plunger pump or outside-packed and connected. INSIDE-PACKED pumps, wit actuated by piston rod working between two water chambers pact; but it is somewhat difficult to keep packing tight, and t packing box for piston rod. This design is common for small for moderate-size pumps. OUTSIDE-CONNECTED AND PACKED plungers, entering opposite ends of water barrel, which is provi partition, plungers being connected by side rods. There are c boxes, readily accessible, plungers are easily removed, pump is in large pumps, weight of outer ends of plungers is carried type is generally used for large pumps, rarely for small.

Lining. For good water, pump barrels and plungers of ha satisfactory; for acid water, linings should be used, with chil resisting bronze plungers. Lead makes satisfactory linings, b apply and often wears rapidly and loosens. Wood lining, ca swelled with pure water, is best, but, because of its thickness castings and is consequently expensive. Various patented en in some cases, but have been little used. Cement lining is state with 75 gr free sulphuric acid per gal (24).

s are of 3 general types. Large single valves, of bronze or faced with leather r, are suitable for low lifts; with high lifts they are apt to wear rapidly from Multiple small valves, usually of bronze, are suitable for high lifts, but more trouble in maintenance. Mechanically operated valves are rarely ept in high-duty pumps, like the Riedler. They permit high plunger speed ice slip. Valves should have low lift, to prevent noise and breakage. Light n suction and relatively heavy springs on discharge valves reduce impact, nore rapid closing permit higher plunger speeds. Valve chambers should eparately from the water barrels, to permit easy replacement, and placed be readily accessible for repairs. Covers should have slotted bolt holes, ged bolts which are swung down instead of being withdrawn.

e. For common direct-acting mine pumps, 12-in stroke and upwards, speed of 100 ft per min is good practice; for long strokes, of 48 in plunger speed is about 125 ft; for mechanically-operated valves, 200 or even more, has been successfully attained. Ordinary pumps in y will run at from 200 to 300 ft plunger speed, but with large loss of , greatly increased slip due to valves not having time to close properly, notable shortening of stroke.

tions. For permanent pumps, solid foundations of stone, brick or concrete, orth while. They should be well built and true, of good materials, and only pump, usually the water end, should be bolted down, the other being left free for expansion. Timber foundations are suitable for small or temporary pumps.

ambers of ample size should be provided. For heavy lifts, air chambers should d on column pipe, as well as on the pump. They are best arranged by put- at bottom of column, connected to an extra length or two of pipe with closed ction air chambers are even more important, to take the blow from the water mp reverses its stroke. They should be beyond the valve chamber, the water nducted directly to air chamber elbow, past chamber inlets. Air chambers must be kept charged with air. This is done by some form mp, either a small pump actuated by the main chanism, or an automatic pump (10). Fig 18 automatic air charger. On the suction stroke, s vertical pipe through inlet check valve *A*, ced by the returning water on delivery stroke check valve *B* to the outlet. To operate, first ve connecting with pump, which must be in , then gradually close until check valves begin For large plants, a small compressor may led to charge the air chambers.

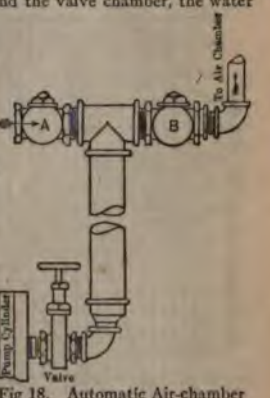

Fig 18. Automatic Air-chamber Charger

on pipe area should be not less than plunger area, the pipe as short and as possible, with no depressions which t as air traps, and with absolutely tight A strainer is always necessary; in its form, a wooden box bored with 1-in les, aggregating not less than 5 times the rea, or a frame of wood or iron covered rse-mesh wire cloth is satisfactory. There are special forms of strainer, in the pipe itself, but, as they are more apt to clog, they must be emovable for cleaning. Suctions of unusual length or high lift should led with a foot check valve, having an area of passage at least equal to he pipe; they are necessary to permit of filling suction pipe in starting . Elbows should never be used; bends where necessary should be of ius, preferably not less than 4 times pipe diameter. All bends should heavy, as they wear rapidly *with gritty or acid* water.

15. Pump Miscellany

Condensers are of 3 types: surface, barometric, and pu
little used in mining, because of its cost and of the large vo
quired. The barometric type, with its necessary height of abo
applicable where considerable quantities of water are run d
elevations to the sump (siphon condenser is a modification of
pump condenser is most used, a combination of barometric h
replacing the tail pipe. The pump is made relatively economi
into the condenser, or by using exhaust steam for jacket h
vacuum may be obtained by exhausting a pump directly into
the exhaust pipe must lie longitudinally in tail pipe, the diame
large enough to avoid undue friction from the obstruction so

In case of acid water, a serious objection to condensing pumps is i
water and its consequent greater chemical activity. Condensing wa
from a part of the sump distant from that heated by the discharge.
ment is largely dependent upon superficial area and shape of sum
water. With neutral or slightly acid water, the condenser may safel
suction, and the heated water be disposed of at once. This course is
deep sumps of small area, which would otherwise become overheate
water, and sumps of sufficient area for cooling, the condenser disch
end of sump and the supply close to pump suction. The economical
for a given case must be determined by experiment. Under favorab
26 in is attained, while with small sumps and very acid water as low
20 in may be most satisfactory.

Column pipe. The economical size of column pipe sho
from cost of pipe, cost of power, quantity of water, and frictio

STANFORD LIBRARIES

The cost of pumping, being manifestly dependent upon ch cost of power, labor rate, height of lift, character of water, and q can not be given in figures of general application. At the colliery, Penn (28), the quantity of water pumped and the co were as follows:

	1901
Water pumped	567 113 616 gal
Average lift	1 141 ft
Total cost:	
Steam	$21 850.46
Labor and supplies	8 915.06
	$30 765.52
Cost per 1 000 gal, 1 000 ft vertical	0.0495
Cost steam per b h p per 24 hr	17.77

The plant was old, consisting chiefly of simple non-condensing pumps to 9 000 gal per min, depending upon the precipitation. It was afterw modern compound condensing pumping plant, at a cost of $120 000, pumping cost to under 3¢ per 1 000 gal, 1 000 ft vertical. At the L Co's Hazleton shaft, the operating cost of the high-duty compound is stated to be 1¼¢ per 1 000 gal, 560 ft vertical lift, or 2¼¢ per 1 000 g cost with the old Comstock Cornish pumping plant (5) is stated as $ for an average of 5 040 gal per min, pumped 1 074 ft vertical, or 19 1 000 ft.

These are probably about the limiting figures, and indicate roughly cost under different conditions.

17. Hoisting Water in Tanks

Probably the first water-hoisting plant was installed in 18 Fidler colliery, of the Pennsylvania Railroad Co, at Shamokin, at least 18 water-hoisting p installed in the Pennsylvani gion (30). This service re use of special shaft compartr with suitable head frames a gines. The tanks are always to 6 ft diam and 1 200 to 4 o There are 2 general types: en bottom-dumping.

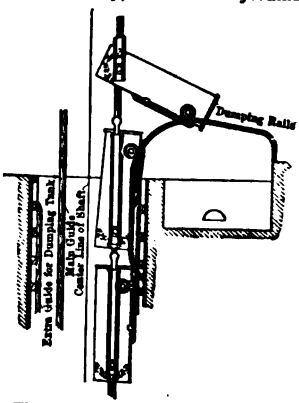

Fig 23. End-discharge Water-hoist Tanks

should be into a basin at shaft collar, having minimum depth o to avoid destructive action of falling water. The bottom-fil large, leather-faced clack valves, opening automatically as tank sump.

Bottom-dumping tanks (Fig 25) are similar in design to the chief difference being in the use of the discharge chute be (Fig 27 and 28). The trouble from impact, in striking the wa with flat bottom of tank and horizontal valves, is avoided in p struction shown in Fig 27, though a side thrust on enterin caused by the shape of discharge casting. This difficulty is re double-discharge bottom casting (Fig 28). On reaching the sur in both designs are opened automatically by a lever operat fixed guide at the landing (Fig 25). These tanks require abo discharge.

Cost of installation at two anthracite shafts (William Pen given below, the proper proportion of shaft sinking, headfram and boiler plant costs, being charged against the water hoist (3c

(Sec 23, Art 3) are most important in collieries. CO_2, and N, the first predominating when much hiefly in the coal seam itself, under pressures rang- t 500 lb per sq in. The quantity evolved is more ily output and fresh face of coal than to the total as is undoubtedly given off from old pillars. Cu mined varies from about 15 to 8 000, or from 0.5 the coal. Averages for the whole coal surface ex- y from 0.2 to 5.0 cu ft per min per 1 000 sq ft. e production of gases may be taken at from 10 to ed, or from 14 to 112 cu ft per min per 1 000 sq ft t 50 to 100% may originate at the face. Within s of this kind may be made on ascertained data, tly unreliable. Moreover, large volumes of gas es liberated in the form of "blowers." In the y contain more gas than bituminous; in Europe very gassy. Quantity of gas probably increases under an impervious cover. Laboratory tests for m samples of coal are of little value for indicating al in place in the mine Reasons are: (a) Large ervoirs in the strata (U S Bureau of Mines, *Tech* pressure in pores of coal is rapidly set free, and a ain but a small part of the gases originally present.

per ton and per sq ft may be established when rate of ed coal to face is known. Assume advance to be 2 ft ace equal 1 ton. Then, each ton daily output requires l requires 0.5 sq ft of face. If all the gas came from the

STANFORD LIBRARIES

working face, the quantity based on output, as above stated, would be fr
ft per 24 hr per sq ft of face, or 0.7 to 4.15 cu ft per min per 1 000 sq ft ol
ing the old surfaces to be 100 times the area of new faces, the maxim
1 000 sq ft would be about 4.15 cu ft per min, over the whole mine.

Relation between firedamp and atmospheric pressure. observed that periods of low barometer, and of increasing outflow from the strata often coincide. The reason is that decreased allows the gas in old workings and in the strata to expand and en Periods of low barometer, especially during rapid falls, should carefully. Exhausted areas or "goaves" of a large mine, perhap with waste, may long continue to give off gas. CO_2 may be produ tion of carbonaceous matter. Goaves act as reservoirs of gas, wh tribute to the ventilating current in case of fall in barometric press (Sec 23, Art 3).

Diffusion of gases. Gases which do not combine chemically will contact with one another, without agitation, even when the heavier gas is bottom. This "diffusive power" assists ventilation and explains the r factory condition of the air in workings where the current is weak. Diffu is opposed by difference in sp gr of the gases, which tends to STRATIFY TH when at rest. Stratification is often pronounced, even within small hei is possible, on entering an old working, where the atmosphere has long b find an explosive mixture of firedamp above the head and a deadly mix damp about the feet, while the air at level of the head is comparatively pu able (Sec 23, Art 2).

3. Dilution of Impurities in Mine Air

Quantity of air required to render impurities harmless: (*a* mines this is based in general on number of men, animals, lights, of explosive used. (*b*) For collieries enough added air must be dilute the gases from the strata. Furthermore, in presence of co with possibility of sudden outbursts of gas from cavities, the dilutio kept far below danger point. Since quantity of gas given off dep on average area of fresh-coal surfaces, the air supply may well be to daily output or number of employes, with due allowance for ga ing from old workings.

Permissible percentage of impurity (Sec 23, Art 6). A mix and air is explosive when CH_4 amounts to from 5.5 to 12.8%. As li to 2% CH_4 may be dangerous, especially in presence of coal du may fall to 10% without causing injury (Haldane), but air is ge sidered unfit to breathe when lights are extinguished, which occur Deep breathing is caused by 3.5% of CO_2 (Thirkell). CO is noxiou sometimes fatal at 0.2%. In general, mine air should not contai 2% of all impurities, which, mixed with 100 volumes normal air, giv (Hygienic effects of mine gases are discussed in Sec 23, Art 5.)

Computation of quantity of air. A synthetic calculation summarize the quantities required to deal with each source of poll pirical estimates are based mainly on number of employes, or on Both methods are uncertain. Even if the requirements of all pos of pollution could be satisfied, an added quantity of air is still allow for leakage and incomplete distribution through the workings

Example of quantity of air required. A mine on an 8-ft seam of steam 15%, and producing but little gas, was slightly short of air at a volume of 2 min, but was fully supplied by 40 000 cu ft. Underground, 197 men and employed, producing 900 tons per 10 hr. Mine was worked by room and pilla

vorking rooms with 125 sq ft of face each, total 10 000 sq ft. main currents traversed 30 000 ft of headings, and swept is are added 320 000 sq ft, in the sides of the rooms, and ft of idle openings; total coal surface exposed, 1 280 000 sq ft ig 1 shows system of ventilation. It is assumed that roof ked-out portions of mine (goaves), covering 750 acres, were rom working places by brattices. (For data on quantities of ntation for quantity of air is as follows:

	= 17	cu ft gaseous pollution per min
	= 17	" " " " " "
	= 8	" " " " " "
1 000 × 14	= 140	" " " " " "
e + 1 000 × 0.1	= 128	" " " " " "
Total	= 310	" " " " " "

required to produce a 2% dilution of impurities, to allow the current, the air required is 310 × 100 = 31 000 cu ft ly with the 29 000 cu ft stated above. Had powder been 3 tons coal, or 30 lb per hr, it would have produced about s per min, requiring an added 500 cu ft of air.

a dangerous quantity of gas the estimate would be:

es, as before,		
17 + 17 + 8	= 42	cu ft gaseous pollution per min
× 112	= 1 120	" " " " " "
ce + 1 000 × 0.8	= 1 024	" " " " " "
Total	= 2 186	" " " " " "

e 218 600 cu ft per min, which seems ample under extreme d surfaces," included in first computation, 92 cu ft per min per inst 1 110 cu ft per min for the dangerously gaseous condition.

egal requirements for quantity of air in circula- air per man, in cu ft per min are: Ordinary build- and gold mines, 20 (Truscott); collieries, minimum ng coal producing states in U S are from 100 to 200, 00 to 500 cu ft per min per mule; Prussian govern- eries, 70. For ordinary collieries allow 100 to 500 Headley); in fiery mines 500 to 600 cu ft per mi-

STANFORD LIBRARIES

plus 200 cu ft for each acre of goaf (Phillips); in French practice, for collieries allow between 100 and 200 cu ft per min per ton daily output. Except in extreme cases the Pennsylvania anthracite mines circulate to 1 300 cu ft per man per min, usually about 500, single fans sometim lating 350 000 cu ft per min. Nearly all bituminous mines in Penn from 100 to 1 000 cu ft, usually about 300. Between 100 and 600 cu ft per min will usually suffice for a colliery, but the extreme limits of requ are probably from 50 to 1 500. (For legal allowances for collieries, Dept Mines, Pa, 1910.)

4. Distribution of Ventilating Currents

Air currents. Mine atmosphere is in equilibrium when at same throughout the mine, and mouths of upcast and downcast shafts are at sam tion; or when the mine air has same density as outside atmosphere, rega difference in elevation of upcast and downcast. Circulation is caused b ence of density, or artifi pressure. Ventilating or MOTIVE HEAD thus p is absorbed by velocity rent and by friction surfaces of passages. duction of pressure by means see Art 10; by means, Art 11 to 18.)

Fig 2. Diagram of Ventilation by Single-entry System

Conditions. To proper ventilation, whe natural or artificial me openings to surface, eith or tunnels, are necessary opening becomes an in DOWNCAST; the other, CAST. A single shaft m both purposes, if divide tudinally into two c ments, in which the air flow in opposite direction for safety there should rate openings, as require In coal regions and els In metal mines having shaft, a second opening is often obtained by a connection with work an adjacent mine (16).

Position of ventilating machine. It is usually on the surface, away from dampness of the mine, and convenient to source of power. When electric available, ventilator is sometimes placed under ground. If air courses are hamp ing high motive head, an auxiliary or BOOSTER fan may be placed in the mine. fan may then be smaller, and leakage due to high pressure reduced. An electri propeller fan (Art 16) is compact and convenient for this purpose.

Layout of airways, in relation to haulage ways and working places of is dealt with in Sec 10. The 4 typical systems of ventilation illustr Fig 2 to 5 apply particularly to coal mining. (Scale of these cuts is dis to show clearly the principles.) SINGLE-ENTRY SYSTEM (Fig 2) involve mum expense for airways, and is adapted to relatively small mines. B

nerally prohibited by law because of the inadequate Chief objections to it are: (*a*) there is no air supply

Fig 3. Double Entry, Coursed System of Ventilation

; the fact that the main current sweeps the entire vor of this method of mining.

stem of Ventilation

Coursed and split ventilation. In a coursed system, some air leaks through the doors, due to imperfect construction and passage of mine traffic. Sometimes openings are purposely left around or through the doors to prevent entire current from entering cross-headings, where it would be superfluous. The mine drag or resistance to ventilation is thus reduced and a better distribution attained. This system requires doors on main haulage ways at each "district." A split system requires less motive head for the same quantity of air, since the effect of splitting is to increase the average area for the whole current, and decrease the length. Quantity of air in the splits is controlled by regulators (Art 6) placed at convenient points. The split system requires overcasts ng currents cross. It is necessary when the return night contain a dangerous proportion of firedamp,

STANFORD LIBRARIES

and is generally preferable for large mines, because the foul air from one d
not drawn through any other. Local conditions sometimes alter this r
some regions the coursed system is adopted, because the cost of making c
in hard roof rock is excessive, and the quantity of air and ventilating
required are small. T
state law provides that

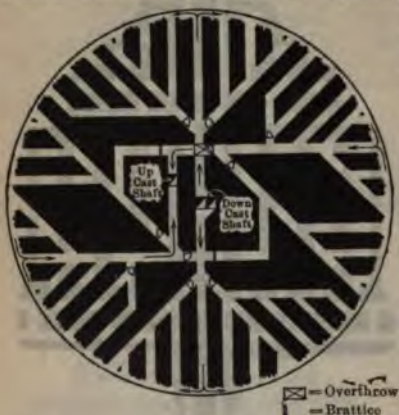

Fig 5. Ventilating System for Longwall Mining

Carrying air to face. In the soft-coal of the eastern U S, air are rarely forced by l pack walls, or other de pass into rooms or The current is carried adjacent haulage road, into the rooms by the tendency to flow throu channels towards a low sure, by diffusion, and turbances caused by t traffic. If these aids sufficient air, canvas are placed at interval the haulage way. In a very "fiery" coal mine it may be necessary to air to the face. In a room and pillar mine this can be done, as in Fig 6, by doors on all rooms of the group to be ventilated, except the first, and cu the last room with an overcast over the haulage way. A pack wall carrie middle of each room forces air to the face. When a seam makes insufficient waste to build a pack wall, wood or non-inflammable brattice cloth is a good substitute.

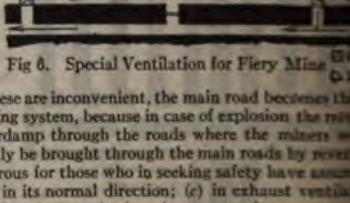

Fig 6. Special Ventilation for Fiery Mine

Exhaust vs blowing system (28). Advantages of exhaust system: (*a*) The foul return current passes through the upcast or outlet direct to the fan, pure air entering the mine by the main haulage ways; (*b*) with blowing fans, haulage ways can not be used as intakes unless doors are installed; and, as these are inconvenient, the main road becomes th This is objectionable with the blowing system, because in case of explosion the re ment of the current forces the afterdamp through the roads where the miners w In emergencies, fresh air may quickly be brought through the main roads by reve current, but this expedient is dangerous for those who in seeking safety have assu the current would be reëstablished in its normal direction; (*c*) in exhaust ventila negative press (depression) at the fan produces in the mine an aver barom pres below that of outside atmosphere; with blowing fans, slightly above. It has b that, with exhaust system, stoppage of the fan increases the mine press; thus exudation of gas. But, this rise of press is small, and its effect in checking outfl (which exists in the coal under considerable press) is probably negligible. It may, h prevent serious flow into working places of accumulations of gas in old workings.

(*a*) If return current contains gas, the fan may be injured by
). (*b*) If intake shaft or entry be wet, it may be obstructed
f ice. In such case, for mines containing little or no gas, the

be (Fig 8) is a U-shaped glass tube about 0.75 in diam, open at both ends, eg turned horizontally. Lower part of U is filled with water. Horizontal nted against air current. Press due to velocity is registered by difference in in the two legs, and measured on the scale. The velocity is

$$v = \sqrt{2gh} = \sqrt{2g\frac{5.2\,w}{W}} = 18.3\sqrt{\frac{w}{W}}$$

where w = difference in water level, in; W = wt of atmosphere. The end towards current has an annular metal cap with sharp edges, to avoid formation

Fig 8. Pitot Tube

Plane of the opening at other end must be parallel to c avoid velocity press. This end may be protected with a of cotton, or better by a thin diaphragm, covering but n the opening. Though these devices prevent serious esc the water columns, readings by the naked eye are inaccura use magnifying glass. By sloping the tube, a greater dis in direction of its axis is obtained, thus facilitating readin for static and velocity press may be placed in the air c connected by pipes with water columns set at a point n for reading. If the horizontal opening of the tube be tur from the direction of current, a partial vacuum is produ retically equal to the press produced by the velocity in position. The observed depression is about half that when the horizontal end current; attributable to eddy currents about the end of the tube.

Anemometer usually employed in mine measurements is a delicate wi oblique blades (Fig 9). Axis of wheel is geared to an indicator, which regist matically the lineal feet of flow of air current during period of observation cator can be disconnected from the wheel by a small lever, so that registration can be accurately started and stopped. Time to attain constant speed must be allowed before connecting the indicator. Velocity is computed by dividing difference in readings at beginning and end of observation by elapsed time.

Fig 9. Anemome

Errors may be caused by variation in friction of the wheel, or by slight bending of the vanes. A table showing error at different velocities is furnished by maker. Instrument should be returned to maker occasionally, to be tested.

Experiments with the wheel anemometer show that the relation between rotations of wheel and velocity of current is expressed approx by the straight-line formula, $v = an + b$, in which, v = velocity, n = number of revolutions in unit of time, and a and b are constants for the instrument.

Another type of anemometer has a vane 3 or 4 in square, pivoted in a frame held at right angles to air current, the velocity is indicated by the vertical angle vane is raised. A quadrant and index at side indicate velocity without comp An attached level enables instrument to be held vertical. This type is sensi convenient, but oscillation of the vane interferes with accurate reading.

Relation between pressure and friction. Friction head or press, r to overcome friction of the air against sides of airways, is expressed equation

$$p = ksV^2 \div a$$

where p is difference in absolute press between ends of air course. To tion head for a series of air courses of different sections is equivalent to t of individual friction heads. If areas of the different sections vary be they may be averaged.

Value of coefficient of friction k depends upon character and ro of sides of airways, upon their curvature, and upon size and form of cr tion. Effect of first two factors is measured by a numerical scale of ro denoted by c in Table 2. Effect of the sectional area is measured by co its mean radius R. Value of k assigned by Atkinson (0.000 000 021 most cases, too great, as shown by Table 2 (1, 10).

Note. The temps C in first column do not correspond with ten third column, except at boiling point (100° C = 212° F), and belo

Quantity of moisture. Saturated air contains all the aq absorb. When two or more gases or vapors are mixed, the p equals the sum of the pressures each would exert if occupyi alone. Thus, if a mixture of air and watery vapor together c exerts a press proportional to the ratio its volume bears to mixture. If H be the barom press and F the press of watery va of mercury), the porportion of vapor present is $F \div H$, and of

So long as the temp of the mixture remains above temp of conde vapor at press F, this proportion remains constant. Relative humic saturation, is the ratio of quantity of vapor present to that which absorbing at its actual temp t, in deg F. The ratio of the vapor mixture, in saturated air, is $f \div H$, where f is the press of saturat ing to its actual temp t, and the relative humidity is $(F \div H) \div (f$ dew point is the temp at which the vapor in any mixture begins to co when t corresponds to the temp of saturated vapor at press F, and relative humidity = 1 (for values of f see Table 3).

Weight of moist air. Weight of a unit volume is expressed by

$$W = \frac{1.293}{1 + at} \times \frac{H - 0.378\,pf}{760}$$

where W is wt in gm per liter, or kg per cu m of moist air; a is a c t, temp in deg C; H, height of barometer in mm of mercury; f, press vapor corresponding to temp t (Table 3); and p percentage of saturat by 100 (Deschanel). In English measures, if H and f be expressed and t in deg F, the wt W in lb per cu ft becomes

$$W = 0.08072 \times \frac{491}{459 + t} \times \frac{H - 0.378\,pf}{29.922} = \frac{1.3232}{459 + t} \times (H -$$

For dry air put p equal to zero. This formula assumes that densi is 0.622 when air is unity. Table of wt of dry and moist air is given

gases vary directly as the press and inversely as the abs cu ft in lb, at 32° F and 29.922 in barom, then wt per barom b, is

$$w = W \frac{491\,b}{(459 + t) \times 29.922}$$

If Q be total cu ft of air circulating per min, and q' and q'' l
second splits, respectively, the velocities are: $Q \div 48$, $q' \div 48$, an
rubbed by total current in CDA equals 56 000 sq ft; by air in fir
ft, and by air in second split, DBD, 89 600 sq ft. If both splits
lators, Art 6), the simultaneous equations to determine Q, q',
velocity head):

$$p' = \sum \frac{ksV^2}{a} = \frac{k \times 56\,000}{48} \times \left(\frac{Q}{48}\right)^2 + \frac{k \times 112\,000}{48} \times$$

$$p'' = \sum \frac{ksV^2}{a} = \frac{k \times 56\,000}{48} \times \left(\frac{Q}{48}\right)^2 + \frac{k \times 89\,600}{48} \times$$

Putting $k = 0.8 \div 10^8$, these equations reduce to:

$$5.6\,Q^2 + 11.2\,q''^2 = 2.76 \times 10^9$$

$$5.6\,Q^2 + 8.96\,q''^2 = 3.86 \times 10^9$$

$$Q = q' + q''$$

whence, $Q = 20\,100$, $q' = 6\,700$, and $q'' = 13\,400$ cu ft per min.

The friction pressures in different parts of mine (Fig 13) are:

From C to D (or D to A), $\frac{ksV^2}{a} = \frac{0.8}{10^8} \times \frac{28\,000 \times 17.6 \times 10^4}{48}$

" D to E (or E to D), " $= \frac{0.8}{10^8} \times \frac{56\,000 \times 1.95 \times 10^4}{48}$

" D to B (or B to D), " $= \frac{0.8}{10^8} \times \frac{44\,800 \times 7.8 \times 10^4}{48}$

The head produced by the different densities between A and l
ft. Of this, the air moving in CD and DA absorbs 1.64 lb, le
equivalent to water gage of 0.069 in, read on an instrument plac
crosscut at D. Also, this pressure measures the friction in level
per sq ft). The split in the slope is assisted by a difference of
amounting to 0.8 lb per sq ft. As the ventilating press at D = c
DBD is $0.36 + 0.8 = 1.16$ lb per sq ft, which equals the friction

Seasonal and daily changes. Weight of downcast
depends upon temp of the outside air as well as of the m
temp is fairly constant, and that of the outside air subject
variation, the strength of a natural air current fluctuates
its direction between summer and winter, and in warm
and day. At periods of reversal there is often tempor
when the temp curve of the outside air crosses that of the

Currents started artificially, when mine atmosphere i
change the temp in some parts of the mine. If this change
so as to produce flow in direction of the temporary cu
becomes permanent. Thus with 2 shafts of equal dep
winter is cooled by the incoming air and a current once sta
as the conditions remain unchanged.

Artificial ventilation is assisted by natural press, when
motion in same direction. If h_0 be the zero to zero pr
system (Art 8), n the density (natural) press, and v the
ventilator; then, total ventilating press $= h_0 + (v^2 \div 2g)$
sign when the artificial current opposes the natural curren

11. Furnace Ventilation

Field of use. When the natural difference in density
cast currents is insufficient to produce the required circu

ficial heat. This ancient mode of ventilation, applicable
ause of cheapness of fuel, was formerly in more general

ing relations between veloc- work. Fig 18 represents an the fan, at a distance r from round its center at a tangen- adial velocity v. u depends d shape of vanes; v depends ed and the cylindrical area the axial width of fan at ra- of the ring, and δ the weight ss of the ring $m = 2\,\delta\pi r v\,dr$ developed by its rotation is f time dt, the radius is increased by $dr = v\,dt$; and the radial o changes dv and du. The forces producing these changes $m\,du \div dt$. Also, the radial deflective force controlling the $\frac{dv}{dt}\Big)$. Total work required is the tangential force applied l force applied through distance $v\,dt$, plus work of overcoming in time d or distance dr is $m\left(\frac{u^2}{r}v\,dt + u\,du\right) = \frac{mu}{r}d\,(ur)$.

he mass of air, being controlled by form and speed of fan, rk, a part of which appears in the form of pressure. Hence, tance dr is the total differential of both static and kinetic of u, v, and h. The real velocity of mass m is $\sqrt{u^2 + v^2}$. e mass is measured by the height h of an air column, the t of the moving air, then total energy of the mass is

$$e = \frac{m}{2}(u^2 + v^2) + gmh$$

$$de = mg\left(\frac{u\,du}{g} + \frac{v\,dv}{g} + dh\right) = \frac{mu}{r}d\,(ur)$$

$$dh = \frac{u^2}{r}dr - v\,dv$$

ies at inner end of vanes are h_1, r_1, u_1, and v_1, the integral

$$h_1 = \frac{1}{g}\int_{r_1}^{r}\frac{u^2}{r}dr - \frac{1}{g}\int_{v_1}^{v} v\,dv$$

press between inner and outer end of vanes, when r is ocities of the air.

nable from the vortex limited by r and r_1 is measured r and a press exceeding actual press at radius r by a head velocities at that radius, In practice this restitution is ortex surrounding the fan wheel and movement in the ex- restitution is never realized. If H be maximum possible city head at r − velocity head at r_1. As the velocity + 2 g and $(v_1^2 + u_1^2) \div 2\,g$, H becomes

$$\frac{v^2}{r}dr\Big) + \frac{u^2 - u_1^2}{2g} = \frac{1}{g}\int_{r_1}^{r}\left(\frac{u^2}{r}dr + u\,du\right)$$

7	55 000 to 75 000		

Efficiency. When useful work is computed by multiplyin
by water gage by the volume delivered, the mechanical effic i
20 and 40%. When the work of producing the velocity is i
work, effic may reach 70%.

Cost of propeller fans, including steam engine, is about $
and $1 200 for a 12-ft fan. With electric motor instead of s
of same size fans is about $350 and $1 400, respectively.

17. Volumetric Ventilators

Types. They are displacement machines, which isolate and remov
air at each revolution or cycle. There are 2 types: reciprocating,
Struve; rotating, including the Fabry, Lemielle, Root, Baker, and
chines are applicable for small volumes of air at relatively high pres
mine resistance is great, due to great length or small cross-section o

ontal, double-acting air pump. There are 2 square cylinders
wheels running on rails. Lower half of each cylinder head
contains inlet valves, the upper half, discharge valves,
thus resembling an air compressor. The machine is
driven from an engine by cranks and connecting rods.

FABRY ventilator (Fig 32) is an old machine (see Callon's "Lectures on Mining," Vol 2), not used in the U S. It has 2 wheels, on parallel shafts, revolving in opposite directions, and inclosed in a casing opening both above and below. Each wheel has 3 radial arms *a*, which fit closely to the casing and are of such length that in rotating they just clear the axis of the companion wheel. Mounted on arms *a* are cross blades *b*, on each end of which are short arc-shaped tips *c*, which make a close rolling joint with each other as the wheels rotate. A volume of air is thus inclosed, between the wheels and the outer

ator

olution. The Fabry machine is the prototype of the modern ROOT ich can be used as either exhaust or pressure ventilators (31).

, the volume delivered is independent of the press; but, as ckward through the joints of the machine also increases. Volu- by dividing the actual delivery by the theoretical delivery, or y between 50 and 90%. Let W = displacement, V = volume e lost by leakage. antages of compressed-air transmission of power for under- red with steam: (*a*) relatively small loss in transmission uced into the mine; (*c*) exhaust air aids ventilation; (*d*) ust steam underground is avoided; (*e*) power is more con- ent work, because there are no radiation nor condensation ined whether in use or not; (*f*) field of application is wider. ower, as in the compressed-air locomotive, and is useful for s after blasting. Compared with electricity the advantages narked. Each has its field, and both modes of power trans- mining. Chief points in favor of compressed air are: (*a*) dusty collieries; (*b*) superiority of pneumatic over electric- aids somewhat in ventilation.

1. Air Compression

ory of air compression is given in Sec 39.)

s. WET COMPRESSORS (practically obsolete in the air is cooled during compression by introducing wate-

into the cylinders. There are 2 types: (*a*) hydraulic-plu bulk and also in form of spray; (*b*) those using spray or j wise similar to dry compressors. Though the air is thorc designed, slow-stroke wet compressors, injected water is mc able. DRY COMPRESSORS, in which the air is cooled by superseded the wet type. Compressors may be: STEAM-I air and steam cylinders are direct-connected; POWER-DRI connected, or gearing, or chains; WATER-DRIVEN, as by im

The compressors cited herein are not necessarily to be consider taken to illustrate standard types; no preference for any partic Table 1 gives close approximations to the actual hp, in 1, 2, or compared with the hp for isothermal and adiabatic compression

Application of different types. For 80 to 100 lb pr compressors are efficient. At 100 lb press, a 2-stage mach in power; at 80 lb, it may save enough to justify its use u For less than 80 lb press, a single-stage machine is gene 100 to 500 lb, a 2-stage compressor is required; from 500 over 1 000 lb, 4-stage. In figuring on the requirements c to specify at least 25% greater capacity than is absolutely for future expansion and prevent decreased efficiency due running. Simple straight-line compressors are furnished capacities up to 1 400 cu ft free air per min, duplex compres used for larger capacity. When power is furnished by ele belt drive, the duplex form is suitable for capacities above

In calculating capacity of stage compressors, the dimensi
cyl are used, Capacity in free air (air at atmos press) per mi
of cyl displacement per rev by number of rev per min, l
For effect of leakage of valves, see Art 10.

Piston clearance. Towards end of stroke in a dry comp
press exceeds that in the discharge pipe, the compressed ai
begins to pass through the delivery valves. Due to clearar
tity of hot compressed air remains in the cyl at end of stroke
this clearance air expands and partly fills the cyl behind th
can enter through inlet valves until cyl press falls below at
fore, since it is never possible to take a full cyl of fresh a
must be made a minimum, say about 1/16 in, or ranging fr
entire cyl volume on short-stroke, to less than 1% on long
(2, 3, 4). In wet compressors, the clearance spaces are filled
not produce this effect.

Losses due to clearance, piston and piston-rod displace
leaky valves, reduce the volumetric capacity to about 70 to
displacement, according to type and physical condition of c

tage Steam-driven Compressors (3)

sors are not suitable for high pressures, because: the ld not be efficiently dealt with by the water jackets of e produces severe stresses; they are more difficult to oling is by water-jacketing, sometimes with ante- . They are classified, according to arrangement of ign, into: STRAIGHT-LINE and DUPLEX.

have steam and air cyl set tandem. They have a flywheel iven by outside connecting-rods from a cross-head between mple or compound, the latter giving better steam economy. ned, requires small space and inexpensive foundations, and lling an important field, the steam economy is lower than in are not self-regulating at much less than 40% of full load. acities up to 1 700 or 1 800 cu ft of free air per min.

furnish examples of standard makes, types, and sizes of of engineers who may not have catalogues at hand.

Duplex compressors usually have 2 pairs of tandem steam with a common flywheel shaft. For same capacity they occu than the straight-line, are better adapted to varying load, and h of speed. In general they are more economical, and with comp cylinders may be run on say 20% less steam than simple com

3. Two-stage Steam-driven Compressor

Two-stage compressors. In these, compression is in 2 step (*a*) by dividing work between 2 or more cyl, there is a more unifo stresses in the machine; (*b*) less heat is generated in each cyl tha press is produced in 1 cyl, and cooling effect of the larger combine of water jackets is greater; (*c*) added cooling is obtained from a 12) between the cyl. Thus, at sea level, and compressing adia gage, a 2-stage compressor delivering 1 256 cu ft free air per m 164 hp, as compared with 184 hp for single-stage (Table 1); sa

Saving of fuel by stage compression is partly offset by greater cost and repairs of the more complicated machines. The point at which economy balances the added capital and maintenance expense corresp per sq in delivery press. Because of the friction losses involved in usi compression in a poorly designed plant may cost more than compressio

Two-stage steam-driven compressors may be straight-line or dup compound steam ends. They are the most important class for mini ver single-stage machines for large plants and high press.

and cooling, the cylinders should be proportioned to divide the n them; that is, there is a "best intercooler pressure" (Sec 39).

ompression: (*a*) Lower aver temp, lower aver press and greater eased safety and ease of lubrication. When high final temp, part increasing wear on piston and cylinder. Sometimes the combi- reaches proportions of an explosive mixture, and, if temp passes s likely. These accidents are rare, even in single-stage work; in ith proper intercooling, they should be impossible. (*c*) Greater al press in the low-press cyl is much lower than in single-stage en expanded to atmos press, occupies less space. Hence, the in- s begins earlier in the stroke. (*d*) Air delivered by a stage com- single cylinder. At constant press the power of air to hold water mp, and in passing through intercooler much of original moisture Hence, there is less trouble from condensation in delivery pipe.

npressors are of Class OC–24. In all of them there are 4 single-st and second stages, forming 1 tandem unit behind 1 ste— rth-stage air cylinders, another tandem unit on the other

STANFORD LIBRARIES

If C = comp cap in cu ft free air per min and L = locomotive free air; N = number of charges required in given time, T; then if $N = 3$, $L = 5\,200$ (corresponding to 100 cu ft of air at 750 lb g $C = (3 \times 5\,200) \div 60 = 260$ cu ft free air per min. When the lo at approx equal intervals throughout the day, one application o otherwise, max and min rates of consumption must be determined.

Compressors in Table 11 are standard Norwalk locomotive cha 3-stage compressor taking air at atmos press is desired. Steam en valves and speed governor. In operation, air is admitted to lar center of machine, for first stage of compression. Water jacket a stract most of the heat, delivering air to second cyl at or near t From second cyl, air is led to second intercooler, and thence into t pression is completed. All cylinders are water-jacketed.

5. Turbo-compressors (8–11)

Turbo-compressors are essentially rotating impellers, ings having on their inner surfaces stationary vanes. In p reverse of the water or steam turbine, the fluid being acte instead of actuating them. They have from 1 to 30 stages separate impeller with discharge vanes and casing, and eac a few pounds only. ADVANTAGES: simplicity, economy of s freedom from vibration (due to the steady, non-pulsating angular velocity, large overload capacity, high effic under lower initial cost and lower cost of maintenance, attendan dom from danger of explosion in air receiver or pipe lines, oil in the interior of the cylinders. The only actual conta bearings. Floor space required is 25 to 33% less than tha machine of equal capacity, and weight is 50 to 60% that o steam-driven compressor. Steam-driven turbos are re constant press. They have a speed governor, the action mented by a fluid-operated piston, with one side connecte

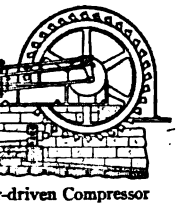
e center, thus balancing end thrust. These blowers are similar pressor, the speed of the impellers being controlled by vary- of a Venturi tube in the intake.

. Water-driven Compressors

e impulse wheel (as the Pelton, Risdon, or Knight) is best t or belt drive for compressors. Their efficiency ranges from about 70 to 85%. Peripheral speed should be 40 to 50% of the velocity of the jet of water.



-driven Compressor

Examples. At the Morning mine, Idaho, high and low-press cylinders are placed tandem on each side of a set of 3 Pelton wheels, one 33-ft and two 12-ft diam, mounted on the crank shaft. The cyl are 33.5 and 18 in diam by 42-in stroke; piston speed, 560 ft. Air is compressed in the low-press cyl to ess, to 90 lb. Inter- and after-coolers are placed in the tail race. l, a 30-ft Pelton wheel drives a 300-hp 2-stage compressor. There nd 18.5 by 30 in, set at 30° to the horizontal. The wheel makes l of 775 ft, the water being delivered through a 1.75-in nozzle (3).

Note. — Cyl proportions in Table 15 are for sea level. For altitudes a diam of low-press cyl is proportionately larger than that of the high-press

7. Power-driven Compressors

Types. These compressors are driven by belt, chain or gearin electric, gas, or other motor. The air ends are similar, in arrang and details, to those of the direct-connected steam-driven type. electric power is low, as in some Western mining districts, this pressor may be more economical than one operated by steam, and power is available, may often be used as auxiliary to main compresse

Relative merits of power drives. Belt-drive is commonest; efficienc Wear of belting must be considered. Silent-chain drive has about 95 % ef

13. Care of Compressors

General. So locate the compressor that parts are readily accessible. Foundations must be level in both directions and, in power-driven machines, the motor and compressor must be accurately alined.

Air valves. Examine at least once a month, to see that there is no cutting, and that the springs, if any, are in good order.

Cutting is caused by ineffective lubrication or grit entering inlet. If the latter, remove the cause of dust, or change position of intake. Keep spare valves on hand for prompt renewal, before wear or defect becomes serious. Leaky discharge valves greatly reduce volumetric effic.

Air lines. Watch closely for leaks, which are costly. A waste enough air to run a 2.25-in drill.

Lubrication must be sufficient, but not excessive.

An air cyl requires less oil than steam cyl of same size. Use best a valves, having a flash point not lower than 500° F. Never use ker deposits in the exhaust valves and ports, as it has a low flash point cause explosion (Art 14).

14. Explosions in Compressors and Receive

Causes: excessively high internal press, due less to the air to that produced by ignition, in compressor, piping, or receive mixture of air and gas from lubricant. The underlying causes ignorance, improper use or kind of lubricant, or faulty design

Lubricants in general use are: commercial cylinder oil, and a n water, each having its proper function. Soap and water has i qualities; if used alone a much greater quantity is necessary than

In a compressor lubricated almost exclusively by soap and water, was found, which readily ignited at 400° F. A very small quantity of of 400° F had also been used, which indicates that the use of soap ventive of explosions. Nevertheless it will clean the cylinder and v ting down, and its use is recommended. All oils give off comb heated. The lowest temp at which this begins is the FLASH POINT, being the BURNING POINT. As ordinary lubricating oils flash at ab below the usual working temp of compressors), special high-flash cyl

Temp due to compression depends upon initial temp, t and the effic of the cooling devices,

gle-stage compressor is found by $T' = T\left(\frac{P'}{P}\right)^{\frac{n-1}{n}} = 0.29$,

ial and final temp, P and P' = abs initial and final press,

D'Arcy's formula for transmission of air in pipes. A gr
of determining the economic size are given in *Trans* A I M E,

17. Air Compression at Altitudes

Effect of altitude. Donsity of the atmos is less at
and the compressor output is diminished because: (*a*
reduced on account of the smaller wt of air taken into
(*b*) due to lower initial press, the heat of compression

Volume of air delivered decreases with barom press,

The relation between press and vol of air delivered by comp
higher altitudes is as follows: If P = final gage press in both
gage press at sea level and at higher altitude; V_1 and V_2 = fi
higher altitude; then, $V_2 + V_1 = [1 + (P + P_1)] \div [1 + (P$
Example: Let $P_2 = 10$ lb, $P = 90$ lb, and V_1 (Table 36) = 0.1

high altitudes. In stage compressors the only clear- tput is that of the intake cyl, and, as loss due to clear- le, this loss per unit of work is less in stage than in

one at sea level (atmos press, 14.7 lb), the other at 5 000 ft . If the first is producing 6 compressions, its final abs press r 73.5 lb gage press. To produce the same press, the other lbs press of 73.5 + 12.2 = 85.7 lb, for which 85.7 ÷ 12.2 = But, at sea level, 7 compressions would produce (7 × 14.7) Since the quantity of heat increases with the final press, compressing from low initial press than from high. Hence, the cyl of stage-compressors is more valuable at high than

18. Measurement of Air Consumptio

Apparatus for this purpose is varied. One consists of 2 l which can be filled with air at any desired press, the drill o be tested being connected to one of them. The tank also con to show in a gage glass. Height of water in the gage is noted, Tank press is kept constant by forcing in more water fro running long enough for accuracy, the drill is stopped, and t in the gage glass again noted. The increase in volume of w of air used, from which the cu ft of free air per min is compu tanks, one being used while the other is being filled with air, of considerable length.

Fig 12 shows a simpler and less expensive apparatus used companies.

120	1.225
.....	.....
.....	.....

Example. — Required to pump 75 gal per min against a vertical head of 60 ft, through 1 150 ft of 3-in pipe. Static press is 60 × 0.434 = 26 lb. Referring to tables, Art 16, 75 gal per min passing through 3-in pipe produce a friction loss of 0.74 lb per 100 ft of pipe; or, for 1 150 ft, 11.5 × 0.74 = 8.51 lb. Hence, working press at the pump = 26 + 8.5 = 34.5 lb. Interpolating in Table 51 between 30 and 40 lb press, 35 lb will require 0.452 cu ft free air per gal, or 33.9 cu ft free air for 75 gal. To estimate compressor capacity, add proper allowance for clearance and other losses (Art 1).

1 (3) may be used for displacement pumps, discharge air pipes from compr intake. Thus, same air is used repeatedly, with some deg 50%. Halsey pump is single-tank pump working on this princi-

free air to operate 30 5-in drills at 9 000 ft altitude, with air 3, one 5-in drill at sea level requires 190 cu ft per min. From rills at 9 000 ft is 20.38; multiplying 190 cu ft by 20.38 gives , which is the compressor displacement for aver conditions, n and leakage losses.

Electric-air" drill operates by pulsations of compressed ven by electric or other motor. The air is not exhausted,

In class GGG, piston rod is symmetrical with piston, and is prevented from rotating by a spline. Class PW has same size cyl as class W, and though slightly lighter will undercut to about same depth. It is built with 3 lengths of piston rod, and is designed for 4-ft veins and thicker, and for hard mining. It has a piston valve, and cyl and chest are cast in one piece. Class PG has 4.75 by 16-in cyl, is built with 3 lengths of rod, and has same valve motion as class PW. It cuts to same depths as class GGG.

Sullivan coal picks are made with 4½, 4¾ and 5⅛-in cyls; they undercut from 4.5 to 6 ft, and weigh 650 to 850 lb (3).

Chain undercutters, usually electric-driven (Sec 16), but Jeffrey Mfg, Link-Belt Mach'y, Sullivan Mach'y Co and others, make air-driven chain cutters for use in gaseous collieries

23. Compressed-air Lo

Note.—Sec 11 deals with all means port, including electric and gasolene l treats of compressed-air locomotives o

Field of work. This type of lo to all mines having compressed-air to gassy collieries, in which electric or fuel-burning machines ADVANTAGES: since the power is stored in the locomotive i wherever track is laid, returning at intervals to the chargin is consumed when the locomotive is idle; the exhaust tend power, greatly in excess of the average, is obtainable by te tank press in the cylinders (3).

General construction. There are 1 or 2 storage tanks etc, are carried on a frame mounted on 4 or 6 driving wh usually simple, sometimes compound. The high-press air passes into a small auxiliary tank, where it is reduced to p before going to the cyls.

Air pressure in storage tanks, 700 to 1 200 lb. Cyl press: simpl compound engine, 200 to 250 lb. Intermediate press for compoun

Tank capacity, for hauls of 1 to 1.5 mile, varies from 50 to 150 it is better to increase the press, rather than the size of tanks.

Reheating (Art 20) is desirable to restore the heat lost in reduci the auxiliary tank; it is essential for compound cyls, the temp of high-press cyl being far below freezing. Fig 53 shows the H. K. Po for compound locomotives. Between the cyls is a shell filled with which the warm atmospheric air is drawn by the ejector action of

in the high-press cyl is thus restored, expanding the air about

1. Purchased Power

Electric power may now be purchased from Public Servi most coal and metal mining regions, an arrangement which is ical than the operation of an isolated plant (1). Cost of SUB-ST FORMING APPARATUS will be from $25 to $30 per kw of rated with $60 to $80 per kw for power plant. This comparison as station, and a power plant of equivalent d-c capacity, but with one or more sub-stations would be required, the purcha save the entire investment for power plant.

Cost of purchased power depends largely on load factor aver to max load. INSTALLED CAPACITY is fixed by peak or plant must supply max demand of all connected loads. OVERH ing interest, deprec, taxes and insurance, is a fixed percentage, vestment. This amount, divided by output in kw-hr, represen kw-hr, which obviously will be a minimum for the highest ratio

On account of distribution of peaks over different periods of the da central stations, serving customers in various lines, have load factors pared with 10 to 20% for the aver isolated mining plant. In the Ka coal fields, W Va, 56 plants, averaging 200 kw, had a load factor of

ity, or 16.4%, based on ratio of aver load to the 5-min integrated per kw is assumed for the central plant, including transmission 60% and overhead cost of 15%, the overhead cost per kw-hr will the usual mine plant, costing $80 per kw, with load factor of 10%, 0.7¢ with a 20% load factor. In these examples, the peak load is capacity. Special rates are made by a number of power com- g their existing plants by purchased power, when the purchaser d steam plant so as to be available in case of breakdown.

is usually in the form of 3-phase a c, and, while haulage ormation to d c at low voltage, other apparatus may be with a c, at low or medium voltage. Induction motors ch are rugged and efficient, and have no commutators or c is also better adapted for lighting, as it can be trans- ge for use in buildings.

yond the power or range of an existing d-c plant are required, operate one or more sub-stations, and if of proper design these the d-c plant, and at night or on idle days either may be shut is especially economical when strikes, breakdowns, or lack of ince a sub-station may be started in a few min, and pumps, fans be operated for a few hr at a cost only in proportion to work plant must be kept in continuous operation. When ADDITIONS quired, an added sub-station unit may readily and cheaply be in- ted plant added boilers, piping, engine, and generator are needed. is an important consideration in deciding between purchased n of a generating plant, and the possibility of failure of the pur- nsmission troubles must be carefully investigated.

r ton of product generally determines whether to use erect a plant; few mine owners have accurate data on r in existing plants, and in case of new operations this must purchased power may be estimated closely from published n in this case the peak load and probable total consump- Where it is proposed to substitute purchased power for an rding watt-hr meter will show the total consumption, and rvals will give the integrated peak for that interval; or a be installed, which will show the sustained peak for any

purchased power is usually based on a FIXED CHARGE of per kw of peak load, plus a METER RATE, which is reduced es. Other rates base the fixed charge on a certain per- e instantaneous peak, or upon the installed sub-station se, the fixed charge is taken as the minimum charge per purchased power in coal-mining districts ranges from 8 for installations above 100 kw. At some western hydro- osts range from 2¢ to 5¢ per kw-hr.

epresent the aver load for a specified time, as 5, 10, 15, or PEAKS are sometimes used, of 3, 5, or 10 min duration, itions.

intermittent apparatus only, as hoists, locomotives, and coal be such that no load would be sustained as long as 5 min. k, or one arbitrarily determined as a certain percentage of the ation capacity, is generally used as a basis. With mining loads capacity, if the 15-min integrated peak is 100%, the 10-min peak e 5-min peak, 110%. For larger capacity, 300 to 500 kw, the , and 106.5%, and for a number of mines (10 or more), the range %, 103%, and 105%. Aver of 56 plants showed 5-min inte- installed capacity, and this arbitrary percentage is often used

STANFORD LIBRARIES

Feed pumps in mining service are subject to the general rule ordinary power plants, where the service requires heavy drafts on t tively short periods. It should be remembered, when selecting p often remote from repair shops; therefore, rugged construction a pumps should be in duplicate.

Feed-water regulators are desirable in mine service, provided will not operate within too narrow limits of low and high water. draft on the boiler would cause rapid addition of a large volume of sequent drop in capacity when it is most needed.

Feed-water heaters are preferably of the OPEN TYPE, as they a moving scale-forming elements, are much easier to clean, and will of the exhaust, which condensate mingles with the feed-water and the boiler. This type has the advantage that waste water, as fr turbine glands, etc, may be piped into it, as it is not under press the closed type may be used, and may be located at any conveni open heater must be not less than 3 ft higher than the feed pump

Water-purifying systems are sometimes installed in connectio and it is claimed are more economical than the cold-water type, as readily in hot water. Purifying plants for mine service must co impurities, as the water supply will often vary from "hard" to relative proportions of surface water and mine drainage.

Fuel supply for colliery boilers may come direct from m breaker, or part from each, or may be received in R R cars. supply and storage therefore vary widely.

If machine cuttings, bottom or roof coal, or road cleanings are loaded separately and delivered in mine cars. If the fuel is scre tipple or breaker, the screenings may often be loaded into mine cars venient in either case to dump the cars into storage bins from a track room floor. But it is often necessary, where fuel is separated at some continuous conveying apparatus for delivering it into bins refuse coal is used it is generally best to crush it to about 0.5 in, as distributes bone, slate, and other impurities, and makes combustion

Utilization of waste heat from bee-hive or Belgian types of coke ov There are a number of waste-heat plants near Uniontown and Brow Run, Pa, 100 bee-hive ovens supply 2 boiler plants, one at middle thus drawing from 25 ovens each way. Radial-brick stacks, 150 ft hp developed per oven depends on character of coal, time of coking With high-volatile coking coals, as the Connellsville, the yield from 48-hr coke, 1.2-in draft at bridge wall, is 16 to 20 hp per oven, with tity or quality of coke yield. With induced draft, as at Ellsworth Ellsworth, Pa, the yield is 20 to 24 hp per oven. With low-volatil Pocahontas and Clearfield, there is no excess gas in the coal, com the oven, and the power obtainable is reduced to 8 to 10 hp per ove to justify the large investment required. At the York Run plant, re are equivalent to use of coal at 70¢ per ton.

Ash handling and disposal at large power plants usually r conveyer (Sec 27). This service is very severe on account of possible it is better to dump the ash by gravity into a dump car

Railroad companies often supply cars and remove ash for ballast roads in mines and around the plant. In flat regions, a tower may cars handled toward its top on a suspended track, filling in track toward the tower. When the top is reached, cars may be run out more directions, and if tracks are properly graded, a small hoisti room will handle cars over a large dump. Fireman or water tender and if car can be run under boilers to receive ashes by gravity, one ash from a large plant. In most small plants, firemen can handl car or a wheelbarrow, but in such case their range of travel must b hauling ash for roads from a fixed dump or by handling it mechanic

8. Engine Room

.ery is determined by: capacity of the plant; whether a c
ted; first cost of installation; operating cost; reliability of
e required.

gine vs turbine. For a plant developing less than 300 kw,
lly preferable. Following tabulation assumes costs as they
change in cost would not alter the relation, the tabulation
comparison. The figures cover standard makes of turbine
engine, direct-coupled to d-c and a-c 300-volt generators.

att, direct current				Cost per kilowatt, alternating current			
0	200 kw	300 kw	500 to 750 kw	100 kw	200 kw	300 kw	500 to 750 kw
	$33	$30	$30	$45	$35	$27	$20 to $15
	22	20	$20 to 30	25	22	20	20 " 30

e the choice of reciprocating engine-driven units for installations
first cost and steam consumption are smaller. For larger units,
d space indicate choice of the turbine. In practice, there is almost
ts as large as 500 kw for mining purposes, and a-c generators,
natural choice for large installations.

dion. Either turbine or Corliss engine can be maintained at good
nitely, if properly cared for, though most types of turbine show
consumption as blades erode or corrode, clearances increase and
Single-cyl slide-valve engines require constant repair and attention
ny. For installations of 500 kw or less, it is usual to operate non-
er plants, condensing is necessary for economy.

Art 14, 15). Choice of type, whether surface, barometric, or low-
kind of impurities in the cooling water. Surface condenser is gen-
it returns the condensate to the feed-water heater. If feed-water
is a great advantage, since only the make-up water, small in
reatment. Barometric or low-jet condenser must be used when

Acid, dirty, or salt water forbids use of surface condenser. As
t mines is dirty and acid, barometric or low-jet is usually installed.
res a larger ratio of cooling water to steam than other types.

ondensing water (Sec 40, Art 15). When the supply of water is
sive power for pumping, or is too dirty and acid for use, even with
, a cooling system may be installed. The water loss in a well-
only the evaporation; it may aver as low as 1.4% throughout the
eed 3%. SPRAY PONDS are usually lower in first cost, are cheaper
and have longer life than cooling towers. Tests show that the
ipated by a properly designed spray-cooling pond is 127 B t u per
fference. Installed cost of a spray system to provide a 28-in aver
year is approx $2.50 to $3.50 per kw of turbine generator served;
nature of the ground makes construction of a pond difficult.

ction of generators for mine service is governed by careful
ocal conditions. In other kinds of service, the practice is
on the basis of continuous load, and to limit the driving
e continuous capacity of the generator can not be exceeded.
y overloads of 100% are often caused by large single units,
and crushers, and the length of the peak will depend on the
rvice. Starting peaks of locomotives or hoists are seldom
an 1 min. The load factor is very low, especially in " "

. For 220 to 300-volt service, it is particularly im- rator be COMPOUNDED, to compensate for line loss. sub-station apparatus, but it is a decided advantage, hen serve a larger territory and maintain more satis- nd. Hence, a motor-generator set is to be preferred

ems, the range of each station is largely increased, and com- . The higher effic of the rotary converter recommends it, d c, unless considerable power-factor correction is requir-d

STANFORD LIBRARIES

This can not be obtained from a rotary converter, since it must not vary from u factor at full load and over, on account of excessive heating of the "tap" coil suitably designed, a synchronous motor may be run as high as 80% leading po

Commutating-pole type of rotary converter (Sec 42, Art 11) is adapted to mine service, because of its enormous overload capacity. factors of 30% and less, which are usual at mines, it is common to use s apparatus which will average half load and occasionally carry peaks of load. With commutating-pole rotaries, the machine may be operate rated capacity, carrying the peaks at overloads of 200%. This gi higher all-day effic and satisfactory service, with a machine of half the These machines may be obtained as standard in sizes of 100 kw and cycles and as small as 300 kw for 25 cycles. They are usually connect and have remarkably good effic; the 150-kw, 60-cycle, 275-volt machi ing 94.7% at 1.5 load, and 93.5% at 0.75 load. Price, $1600 f o b, facto

7. Transmission Lines (See also Sec 42, Art 13)

Calculation of d-c 2-wire circuits: if I = current in amperes, or wat L = length of transmission, ft; V = volts lost in transmission; then cir in conductor = $(22 \times I \times L) \div V$.

For haulage work, where the track forms the return circuit, the rail capacity at least equal to that in trolley and feeders. Steel rails in general have 12 t sistance of copper, and for 2 rails will be equal to 20 000 cir mils of copper per Thus, a track of 40-lb rail will be equivalent to 800 000 cir mils. When capac and rail are unequal, the drop in each should be figured separately, using $V = 11 \times I \times L \div$ cir mils, in which case V is the drop in half the circuit. is distributed, L represents aver distance.

Calculation of single-phase a-c circuits. Formula given above ma as reactance may ordinarily be neglected. But the current, represented h watts $\div E \times$ pf, where E = volts between conductors and pf is power fa circuit. For 3-phase circuits, universally used for mines, the current I i will be kw $\times$ 580 $\div E \times$ pf, and the size of wire in cir mils = $19 \times I \times$

Example. To transmit 500 kw, 3-phase, 6 600 volts, 85% pf a distance of 20 300 volts loss. Current in lines will be $500 \times 580 \div 6\,300 \times 0.85 = 54$ am mils = $19 \times 54 \times 20\,000 \div 300 = 68\,400$, which is nearest a No 2 wire. W ties are large, reactance must also be considered (2), as the losses from this exceed resistance losses (Sec 42, Art 13).

Permissible losses may be determined from standpoint of economy mission or from operating conditions. It is common practice to fig lines with a loss of say 10%; but large saving in transmission cost may by considering that, as a general rule, for best economy the value of should approximately equal the INTEREST charges on the conductor.

Example: Assume 500-kw aver load at 500 volts, delivered 1 000 ft with 5% power costing 2¢ per kw-hr, this loss amounts to $4 320 per year. The requi from above data, is 5 200 lb, which, at 15¢, will cost $780, and interest on this $36.80. Total yearly cost of delivering this power is $4 367 per year, of which charge is about 1%. It is evident that a much larger investment in copper wi power loss would be more economical. For trial, assume 3 times as much c 0.2 as much power loss. Interest charges will then be $234, power loss $86, transmission cost is $1 098, a saving of $3 269 per year. Evidently a saving of might be effected by still further reducing the loss to about 0.5%, but this wo an investment of about $4 000 for added copper. On BASIS OF COST the in above cases would be large, as the copper required for least annual cost woul 9 000 000 cir mils. An even larger installation would theoretically be justifi power cost higher or copper cost lower; on the other hand, with power cost size of conductors would be halved.

OF VIEW, it is advisable to allow not more than 33% drop at max
actory operation of mining machinery under the worst conditions,
ons will be greatly improved. This appears an excessive drop, but
ge number of mines show max drop of 50% and over. With 10-hr
this max loss represents an aver loss of 6.6 to 10%. With poten-
the mine openings, the minimum voltages underground will be 200
isfactory operation of machinery designed for 220 and 500 volts.
ial in coal mining, makes a large copper investment inadvisable.
full-rated voltage should be maintained, since output and torque
as the square of the applied voltage. With step-down trans-
ed voltage taps may be used, line drops of 10 to 15% may be
l, and particularly with synchronous converters, it is best to
for not over 5% drop at rated capacity, which should be taken
ated peak. Where this is not known the continuous rating of
ted may be used.

ation of transmission lines for either d c or a c should be
accessibility, economy, and safety.

ction and repairs is of first importance, and if conditions permit
ays to make a considerable detour, as it will facilitate finding
se of ground or short circuit, a repairman can cover the ground
horseback or with automobile. In many cases, particularly in

In operation, the aluminum type demands considerable attendanc regular and frequent intervals, the interval being much shorter in warm arresters are in a warm place. Though protection of primary apparat arresters, if step-up or step-down transformers are used these largely and a cheaper form of arrester, as the horn-gap, in connection with cl substituted for the electrolytic.

Choke coils are desirable for protection of all classes of electrical lines. They should be connected between lightning arrester taps an protected, on both main and sub-station ends of a-c lines, and also in co d-c feed lines. When in series with cables, the inductance of choke c cable may produce a condition of resonance, building up very high pote with an arcing ground, as in charging an aluminum arrester.

Cost of choke coils: 100-ampere, 6 600-volt, single pole $15.75 eac 200-ampere, 13 200-volt, single pole, 26.10 "

Ground wires are an efficient protection for transmission lin are used, partially surrounding the lines, they afford complete lightning, though arresters will still be necessary to prevent tro grounds. Pole lines usually have a single ground wire, support top on a bayonet or ridge iron. On steel-pole lines, with 2 or m on pole lines in exposed locations, 2 or even 3 ground wires sho above the lines, one at top in the center and one at each side.

In moist climates or where exposed to fumes and gases, as from coke ground wires should be of copper; elsewhere they may be of galvanized s dipped, 3/8 or 7/16-in diam, and should be tied with wire of the same mate WITH STEEL. Good groundings may be made at power plants, as to wa at sub-stations and on transmission lines it is often necessary to drive ground, or to bury copper ground plates. Salt around pipes or plate sistance and keep ground moist. Galvanized iron pipes, 0.75 to 1-in d ft in earth, will have 15 to 20 ohms resistance. Where good grounds c for a considerable distance, larger and better ones should be provided each end of such section (2).

8. Underground Wiring

Underground wiring must in general be supported from n walls, be safeguarded against falls of roof, and be so installed opportunities for contact by workmen and horses.

Feeder wires and cables should be insulated, preferably varnished cloth, though for potentials under 300 volts braided be used, filled or impregnated with waterproof compound.

As all types of insulation are affected by ACID WATER (rubber least, var feeder cables must be protected from water and supported on insulator sides, as though bare. Wet-process porcelain or glass insulators mus process knobs are attacked by mine acids. Where roof is of conve height, feeders may be supported from it by expansion bolts, or by lag plugs. If roof is high or irregular, or apt to fall, wires may be carried driven into walls or ribs, or on 1.5-in iron pipe, driven into holes bor neither roof nor rib is suitable, posts may be set against rib to support while in extreme cases, with frequent falls or caves, armored cable may bottom. Feeders should preferably be located on haulage roads beh than on air courses or parallel headings, so they may be readily inspec

Alternating-current lines should be of 3-phase insulated high voltages (above 600) must be lead-covered or armored. S have the lead or armor grounded, and are usually carried on mess feeders, even when supported from roof, should be carried clos where least liable to injury from falls of roof or rock.

Fig 6 is a diagram for obtaining effective wt of flywheels. The heavy lines assumes 20% drop in speed to deliver 25 000 hp-sec, w assumed as 4 ft, with set running initially at 600 rev per min, and shows that an effective wt of 39 000 lb will be required. Use of conical drums often improves the load curve by reducing the acceleration peak and compensating for wt of rope, which is a large factor in deep shafts (Sec 12). Electrical shaft hoisting is chiefly an electrical problem, and the design of drums will depend on the most economical duty cycle.

Fig 5. E A

Control of induction-motor hoists may be by liquid rheostat or magnetic contactors.

Liquid rheostat consists of a tank, filled with electrolyte (as soda or salt water) arranged to carry electrodes, usually triangular or trapezoidal. Electrodes are preferably fixed in position, and the electrolyte, circulated by a small pump, rises and falls in the tank. Electrodes are connected in the wound rotor secondary circuits, and motor torq the submerged area of electrodes. As the secondary circuit must trode tips remain submerged. The primary switch of the motor is operating a weir; the first movement of this lever closes the prim

eir controlling overflow of the electrolyte, allowing the liquid to Assuming the weir to be raised at once to its full height, the rise

Control of d-c hoist motors by field control of variable-voltage generator is by rheostat in generator field, which is separately excited. Generator is of interpole type, and readily commutates current from o to max voltage, positive or negative, while running at a constant speed. Hoist-motor field is separately excited, so that its speed varies directly as impressed voltage. Same mode of control is used for IGNER SYSTEM, with addition of a slip regulator in the induction g the set to slow down when heavily loaded, thus drawing for all loads above a fixed capacity.

mple form consists of a liquid rheostat, in series with main in-y, with electrodes raised by a small induction motor in series with rrent, usually through series transformers. These electrodes are t, with normal current in main motor, they are completely sub-resistance in main-motor secondary. When line current exceeds the torque of the small regulator motor is correspondingly in-trodes and thereby increasing the secondary resistance of main and allowing flywheel to deliver energy to the d-c generator.

Details. FRAMES may be of C I, riveted steel plates, solid steel slabs,
type. Riveted-plate and slab frames are unbreakable, as in collision.
frame has the advantage of affording ready access to brakes, sand ri
apparatus, and gives best ventilation. Bearings, for journals, axle
motors, and armature shafts, must be carefully designed to exclude du
to give good service with minimum attention. JOURNAL BEARINGS are
removable when weight is taken off, and lubricated by waste-packed oi
BEARING LININGS may be of bronze or babbit, lubricated in the same
BEARINGS are preferably BALL BEARINGS, though bronze-lined waste-pa
also successful. It is highly important that the wear on these bearings
cause wear shifts the air gap, affects commutation and gear mesh, and
armature by rubbing the pole faces. Well-designed and constructed b
eliminated such troubles almost completely on small locomotives, a
standard practice on large ones of 75 hp and over. The limited spac
locomotives makes ball bearings desirable. MOTORS for mine locomoti
in general design from standard railway motors, though because of t
used, the coils, commutators, and brushes are often heavier for the
should be form-wound, interchangeable, impregnated, and baked, makin
waterproof and increasing the conduction of heat from the copper cond
narrow track gages require very compact motors, making it increasingly
sufficient heat-radiating surface. GOOD COMMUTATION is difficult to obt
rough track, many frogs and switches, and severe peak loads, both on
on heavy grades. COMMUTATING-POLE MOTORS are very advantageous,
ing due to overloads and minimizing effect of jar and vibration on
brushes. They also have a higher continuous rating, due to lower ma
armature core and pole face (8). Where gear faces are reduced on v
special heat-treated alloy steels may be used, and would doubtless be
standard practice. Tool-steel gears and pinions, costing about 1.5 to 2
ordinary forged steel, are guaranteed for 3.5 times greater mileage.

Controllers are of the magnetic blowout type, with separate li
ders, for speed control and for reversing.

Most controllers have both series and parallel connections on reverse c
connection is of no special value except for very light work, as motors wi
factorily in series unless mechanically connected, as with side-rods (9).
lers use double contacts, with separate blowout magnets for each resistance

Resistances for speed control are practically all of the C-I grid typ
alloy ribbon, packed with asbestos, is still used on some small sizes.

ced. Resistances should be placed at the ends of locomotives, d, and not above or near motors or cables.

tion of electric locomotives depends primarily on motor also on type of wheel, wt of rail, amount of sand used, etc.

Maximum available for starting depends on the wt of locome cases, with sharp sand, is as high as 50% of the wt; . Without sand a COEFFIC OF ADHESION of 25% may be heels, or 20% for chilled C-I wheels.

ion is 25%, and motors are available which will exert this drawbar hr with a temp rise of 75° C. This so-called RAILWAY RATING is h of haul is short and grades not excessive, so that sand is unnecesand approximates 10 hp per ton, at 8 miles per hr. On long h adverse grades requiring much sand and where motors can not the standard 1-hr capacity will not suffice. In such cases, the ous service is specified, and should not be less than 6 hp per ton.

13	35·5	"	42	3 620	30	36
15	35·5	"	"	3 805	35	36

Standard equipment includes single-end control, 1 trolley, c incandescent headlights, with wheels inside frame. 3-motor l with wheels outside frame. All prices include freight east of Miss headlights, $40 ea; rolled-steel wheels, 5-ton loco, $40, 7.5-ton $60 to $80.

Gathering locomotives are of the same general type locomotives, with the addition of a trailing-cable or rope, motive to enter rooms or headings where no trolley wire

These locomotives require much less head room than mules, men will gather from 2 to 5 times as many cars as 1 mule with dr greatest where grades are worst. Where the seam is only 3 to great, because for mule haulage the top must be taken down head room. Gathering locomotives should handle 85 to 150 ca where several cars may be placed at once in each room. The h so that cars are delivered and removed regularly; it is usually n ings in pairs so that on one trip empties may be placed in one an the other, rather than to handle empties and loaded cars in the

Cable-reel type has a 2-conductor twin or concentric trailin trolley and to rail at the room neck, and paid out as the locomoti the cable as reeled out lying on the floor. A single-conductor with the room track forming the return circuit. On returning, on the reel, a tension of 10 to 20 lb being maintained to prevent the cable. In some types the reel is driven by a friction clutch but a later form drives the reel by a small series-wound motor tinuous connection across the line, maintaining uniform tensio length. Cables may be overrun and injured by the friction-clu cause wheels to skid, or by the motor type should the current b be used for pushing empty cars or pulling loaded cars up grade

Traction-cable or crab type carries a small and very compact eration, the "spragger" or trip-rider pulls the wire rope into the motorman winds up rope, pulling car out to locomotive on head cars may thus be hauled up grades too steep for locomotives. Th grades are against loaded cars only; in special cases, locomotive

Note (for following table). — Standard equipment includes 2 cast-chilled wheels, and 1 trolley. Cable reel carries 500 ft sing Crab reel carries 300 ft wire rope, and is driven by separate 7.5-hp on crab reel, add $125 to crab and combination type prices. for 3 to 6-ton locos, $40 per set, for 7 and 8-ton, $60 per set; slee $60, for 7 and 8-ton, $80.

6	3 000	100	2 880	58	2 760	39	2 640	29	
7	3 500	117	3 360	67	3 220	46	3 080	34	
8	4 000	133	3 840	77	3 680	53	3 520	39	

Example. Assume the locomotive must gather 120 cars in 8 hr, to the face. Trains are of 10 cars, making total number of trip 5 200 lb; length of haul from side track to first room, 600 ft; dep of haul on entry in front of rooms, 400 ft. Rooms are level an against the load. Distance the locomotive travels, and distan different parts of a trip, are given in tabular form:

	Equiv length of haul, ft	
	Loco	Loaded train
Side track to first room....	600	600
On entry in front of rooms.	400	400÷2=200
In rooms.....	10 × 250 = 2 500	
Loaded train weighs	$\frac{5200 \times 10}{2000}$ = 26 tons	

Kw-hr required for each part of haul over which LOCOMOTIVE t 1 000) × loco wt × kw-hr (read from curve). Per trip for level 5 × 0.025 = 0.312. Per trip for 1.5% grade, (1 000 ÷ 1 000) ×

Kw-hr required for each part of haul over which TRAIN travels × tons of loaded train × kw-hr (read from curve). Per trip on le 26 × 0.026 = 0.17. Per trip on 1.5% grade, (800 ÷ 1 000) × 26 × 0 per trip: locomotive, 0.467; train, 0.952; or 1.419. Hence, tota

To allow for decreased capacity of battery when discharging s in gathering service, switching extra cars, pulling empties and locomotives from charging station to working place, and running kw-hr obtained by calculation is multiplied by 1.35, to give the capacity at normal discharge rate, which in this case is 23 kw-hr. Consult Table 12 for battery capacities.

Table 12. Kw Dis
(Normal batt lo

Edison	
Type	Kw-h
63 A–4	11.
63 A–6	16.
63 A–8	22.
126 A–4	22.

Note that for above example the nearest battery capacity with least number of cells is 63 A–8 Edison, or 48 MV 15 Ironclad. Either will need at least 1.5-hr boosting charge, whenever the battery has been in use for 4 hr, in which case Edison battery will have 15% greater capacity, and Ironclad 25% greater capacity than given in table. Example shows how Fig 8 is used when calculating battery capacity required for gathering, and it is evident that this method can be used for any kind of installation on any kind of haul.

Successful installations of storage-battery locomotives have be Mining Co, Terre Haute, Ind; Bunsen Coal Co, Clinton, Ind; Pitt Pa; Consolidation Coal Co, Fairmont, W Va; Sterling Coal C n Mining Co, Kellogg, Id; Anaconda Copper Mini

tric Pumps (For "Mine Drainage," see Sec 13)

s best adapted for motor drive are the triplex single-acting, g, quintuplex single-acting and triplex double-acting. Single- er types, or duplex single-acting, may be motor-driven, but should be smoothed out by large air chambers on discharge t should be low, or vacuum chambers used on suction line.

r pumps (Sec 13, 40) are driven through single or double reduction s, pinion shaft should have an outboard bearing, or preferably be ft and provided with independent bearings to eliminate chattering oid, cloth, or rawhide pinions should be used on small pumps with s, as these reduce noise and vibration and eliminate crystallization

red pumps should be 85 to 90%, not including motor, but it uced by tight packing, worn gears and improper lubrication.

turbine pumps (Sec 13, 40) are driven direct from motors, exible couplings, the latter being used only where units are e.

high rotative speeds, bearings must usually be of self-oiling type, notors, and though pumps are preferably designed for hydraulic ust bearings should be provided, of ball or marine type. When nature must be in electrical balance under load, otherwise end thrust st bearing. EFFIC of well-designed centrifugal pumps ranges from pumps, 70 to 80% (10). SUCTION LIFTS for centrifugal and turbine eed 20 ft for best results. These pumps are most suitable for single rawing water from a number of points, with long and branching r plunger types are necessary unless lines can be kept tight and all

ng pumps usually require constant speed; hence, a-c induc- r compound types are suitable. Induction motors are prefer- r large main-station service. On account of the general use it is convenient to use self-starting compound-wound d-c mps, and in case of interruption by overload or short circuit rt without attendance, when current is restored. COSTS of suitable for pumping service, are given in Tables 13, 14 and

ction motors for centrifugal and turbine pumps may be by COMPEN- starting torque will not be high, and, unless motors are of large size starting current should not be objectionable. For larger motors, h a number of starting taps, connected through a DRUM-TYPE CON- or, wound rotor-type motor may be used, with starting resistance in gh for underground use the SQUIRREL-CAGE induction motor is prefer- plunger pumps, with gear drive, compensators may be used on small ticularly if cloth or rawhide pinions and flexible couplings are used for ears at starting. For larger pumps and high press, some MULTIPLE- , with a by-pass valve in discharge, to relieve press when starting.

und-wound and with interpoles, may be thrown in circuit without 5 hp, in which case the starting torque corresponds to that of squirrel- , and strain on gears and pumps is very great. SERIES CURRENT- commended for sizes larger than 20 hp. These are made in sizes and 200 hp, 500 volts, and are especially applicable to operation in r SWITCHES; these switches may also be used with self-starting apacity, and in larger capacities operate the pilot switch only for the it starter. Use of float switch with series current-limit control r attendance (except for occasional inspection), and insures proper arting current can not exceed a predetermined amount, required to d.

16. Mine Lighting by Electricity

Lighting of mine buildings, as offices, stores, shops, and dw
at low potentials, preferably not over 125 volts, on account of
and greater safety. This involves use of a-c, with distribution at
of 2 200, and step-down transformers of suitable sizes at cente

Large buildings, as stores, should use 3-wire system at 110 to 220 vo
costs. Dwellings may be grouped in blocks of 10 to 20 or more for
transformer. TUNGSTEN LAMPS are recommended, as giving better
half the current used by carbon lamps (Sec 42, Art 15).

Underground lighting system is commonly taken from mine
in which case 110 to 125-volt lamps should be used, connecte
quired. CARBON LAMPS, rated at about 3.6 watts per c p, giv
the fluctuating voltage of mine circuits.

Storage-battery miner's lamps have been widely introd
since 1914; on Jan 1, 1916, over 15 000 were in use.

Lead-battery lamps are made by the Witherbee Igniter Co, Springf

COST OF LAMP complete is $7 to $8.50 each, according to type. Charg
racks, meters, and accessories, cost $3 to $4 per lamp capacity. To
installation ranges from $10 to $12 per lamp, in quantities of 250 or

Lamps may be charged in groups of 80 or 90, from 250-volt mine cir
able rheostats. Small motor-generator charging sets, of 1 kw capacit
stalled, cost from $300, for 3-kw, to $500 for 6-kw capacity. COST o
labor, repairs, and charging current, should not exceed 4¢ per 12-hr
charge to miner per lamp is 5¢ per shift, leaving a balance to offset
and to cover interest on investment. Large installations have been m
Reading Co, Pottsville, Pa, Keystone Coal & Coke Co, Greensburg,
Co, Pittsburg, Pa, and Rocky Mountain Fuel Co, Newcastle, Cal.

17. Miscellaneous Power

For application of electric power to crushers, air compress
and screens, jigs and other apparatus in concentrating plants a
shop machinery and similar work, the a-c induction motor is pr
except where variable speed is required. Induction motors
less care and attention in dusty or damp locations than any
higher aver effic.

Direct drive, through flexible coupling, is especially desirable for
crushers, on account of the rapid change in load causing belts, chains,

ain alinement. EXAMPLES: Large crusher motor drives, 300 and
e crushers (Sec 35, Art 11) and 0.25-in screen, are used by the
ary, W Va. Compressor motors, direct-connected or belted, of
by the Rochester & Pittsburg Coal & Irón Co, near Indiana, Pa,
, with synchronous motors, direct-connected, by the Anacónda
e, Mont.

AND DRAFTING INSTRUMENTS

1. Tapes and Rods

commonly 50, 100, 200, 300, or 500 ft long. The 50 and ally thin steel ribbons; the longer tapes are thicker and ability of kinking and to stand rougher usage. The lighter throughout in feet, tenths, and hundredths; the heavier are otched sleeves, etchings, or brass rivets at every 1-, 5-, 10-, st foot on each end being often divided into tenths. When s alone are marked, the last 5, 10, or 20 ft is usually graduated e 200 or 300-ft tapes are made 201 ft or 301 ft long, the addi- aduated into tenths. In most lighter tapes the zero-point some at the end of the steel ribbon, while in others it is 0.2 The heavier tapes are equipped with handle for each end, being marked. Bronze tapes are manufactured for use in mines. Metric tapes are in lengths of 10, 15, 20, 25, 30, hem are graduated in feet and inches on reverse side. The ight metric tapes are 15 and 30 m, the heavier, 25 or 50 m pes are carried on reels; tape reel should be of ample size, tape fills a larger reel than a clean one, and long tapes used at mines are also often used underground, where they are nd dirty.

th thermometer for temperature corrections, and with spring bal- ring amount of pull, are used chiefly in city surveying. Broken y riveting on back of tape a piece of old tape of same width; com- s are sold for this purpose. Tapes graduated in feet and inches building construction.

tapes are common; the former stretch readily and are useless llic tape is of cloth with fine brass wires woven into it to prevent usually graduated into feet, tenths, and half-tenths, and made in ; sometimes with feet divided into inches. A 50-ft metallic tape h as 0.5 ft, owing to rough usage and alternate wetting and drying; only for rough work.

-ft tape and box is from $5 to $15. The heavier tapes, exclusive per 100 ft, and can be obtained up to 1 000 ft; the ordinary reels 50 to $15; certain special reels for mine surveying cost as high as o ft long cost $2 to $3. Bronze tapes are a little more expensive es.

from 3 ft up are useful in the field, for accurate measuring when y at the 5-, 10-, or 20-ft points, are used.

rements recorded in tenths and hundredths of a foot into inches wing equivalents may be used:

oot = 0.01	0.08	0.17	0.25	0.50	0.75
= 1/8 −	1 −	2 +	3	6	9

morized, decimals of a foot may be quickly transposed into inches, 0.75 ft − 0.03 ft = 9 in − 3/8 in = 8 5/8 in.

trument attached to a wheel of a vehicle, to record number of wheel in traversing between two points; revolutions × circum-

trument to record the distance traversed by a person carrying it; erent lengths of pace.

easuring distance (see Art 22).

STANFORD LIBRARIES

Leveling rods are of two types, TARGET and SELF-REAI rodman, latter by levelman. Commonest forms of targe the New York, and the Philadelphia; the Philadelphia self-reading rod (Fig 1). Most rods are made of two they may be extended. The target of Boston rod is pe one strip of the rod; this requires that for readings highe rod the rod must be inverted, which introduces an erro so that the target is not in correct place with reference scale. The other target rods are always used right-side

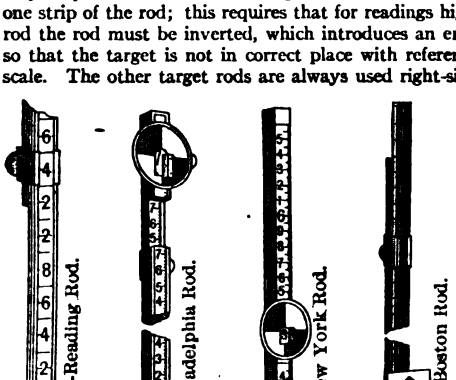

Fig 1. Leveling Rods

that it can be read through telescope by the levelman of rod are usually of a definite height (0.06 or 0.08 ft) 0.01 or 0.02 ft, thus aiding levelman to estimate hundredths of a foot or even closer. Self-reading rod for ordinary work has many advantages over target rod. A rod equipped with clamps having screw-heads, which lie close to rod and are protected by a metal guard, is preferable to a rod with outstanding screws, especially if rod is to be shipped from place to place. Ordinary leveling rods cost $9 to $16.

Stadia (or telemeter) rods are usually of soft pine, with a face 3 to 4 in wide, on which distinctive diagrams are painted, to be clearly distinguished at distances of 1 000 ft or more. For stadia sights not greater than 300 ft, the ordinary Philadelphia rod is suitable; for sights up to about 600 ft, either the first or second rod shown in Fig 2 is suitable; for longer sights the third rod in Fig 2 is best. Many surveyors make their own stadia rods, because those sold have too narrow a face, and graduations, and are not marked with clear, distinct

tion, stadia rods are frequently in two parts, hinged at hinged, it is well to provide a hard-wood cleat for back of ed joint. In Fig 2 two of the rods have cross-hairs marked . they are read (Arts 22 and 23).

2. Verniers

determining fractional part of smallest division of a scale it can be estimated by eye. The simplest form (used) is shown in Fig 3, where one unit on rod is divided The entire length of vernier equals space occupied by 9 hen the vernier length be subdivided ne division on vernier will be 9/10 as n scale. (*b*) Straightening needle and centering pivot- ich is detected by noting whether S end reads 180° from N end; e due to a bent needle or a bent pivot-point, or both. A bend in d by reading S end of needle when N end points at some selected eading N end when S end points at same graduation. Bend the where metal is soft until ends read the same in either position r reading 180° apart at either trial). The pivot may be centered e position of maximum difference between end readings in different ding pivot until any two end readings agree. (*c*) Re-magnetizing it with a bar magnet from middle outward to ends, applying N S end of needle, and *vice versa*.

ss is a hand instrument for obtaining roughly the bearing of a inds, PLAIN and PRISMATIC. Former is much like surveyor's com- ally has no sights. In prismatic compass the graduations, instead ox, may be on a card fastened to needle (like a mariner's compass) This compass is generally provided with sights; bearing is read or folding mirror, at same instant that compass is sighted along es for surveying range in price from $10 to $60, the latter being ructed compasses, to carry in pocket for use with a tripod. The mpass costs from $25 to $75, including tripod.

4. Transit and its Adjustments

it (sectional view, Fig 5) has two spindles, one fitting in- h of which is fastened a horizontal circular plate; the outer lower plate, on which is graduated circle, and inner spindle to which the verniers and standards holding telescope are on of these horizontal plates is controlled by clamps and upper plate are two spirit-levels; the plates are leveled by ling screws, working between base and lower plate. Tran- bubble and vertical arc are called ENGINEER'S (OR SUR- a plain transit lacks these attachments.

compound objective, and an eye-piece composed of 4 lenses, recting transit, two lenses if inverting; an inverting instru- tter illuminated field. Between objective and eye piece is eld in its concentric position by four opposing screws tapped ds being outside telescope tube.

STANFORD LIBRARIES

Special attachments are: (*a*) Dark eye-piece for observing sun. nal or prismatic eye-piece for sighting high altitudes. (*c*) Reflector a telescope for illuminating cross-hairs when working in dark. (*d*) screw for measuring rates of grade directly. (*e*) Stadia hairs, which extra horizontal cross-hairs used in measuring distances by stadia. attachment for determining meridian by observation on the sun.

Precautions in care of transit. Neither tripod legs nor their shoes should to become loose. In taking instrument out of its box, always lift it by placing

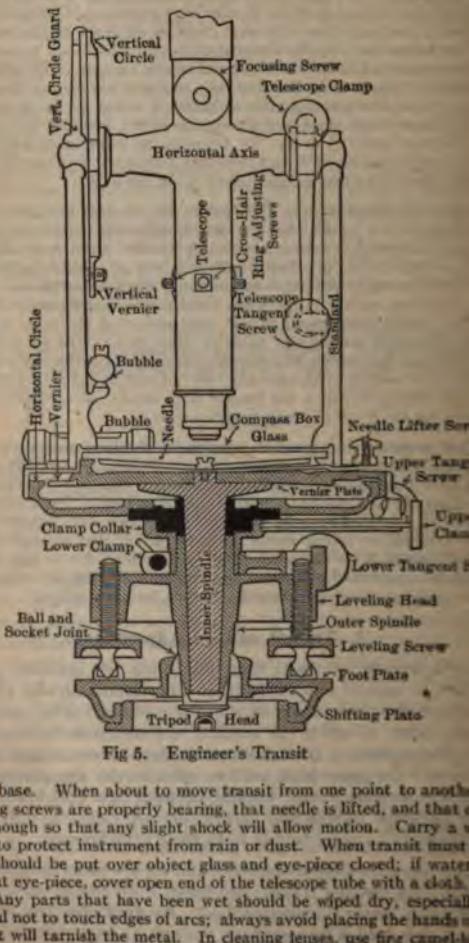

Fig 5. Engineer's Transit

beneath leveling base. When about to move transit from one point to anoth that the 4 leveling screws are properly bearing, that needle is lifted, and that set just firmly enough so that any slight shock will allow motion. Carry a bag at all times to protect instrument from rain or dust. When transit must in rain, the cap should be put over object glass and eye-piece closed; if wate telescope, take out eye-piece, cover open end of the telescope tube with a cloth it to dry out. Any parts that have been wet should be wiped dry, especial arc, but be careful not to touch edges of arcs; always avoid placing the hands graduations, as it will tarnish the metal. In cleaning lenses, use fine camel-h for screw threads, use stiff tooth brush and apply a very little watch oil afte

exposed screws. Carry transit in a box when traveling on a g, always enclose transit in its case, pack paper about it, and box packed with excelsior. Cover tripod threads with wooden ing.

ie transit are: (*a*) to make plane of plate bubbles per- axis of instrument; (*b*) to make line of sight perpendicular to make horizontal axis perpendicular to vertical axis of

Bring plate bubbles to centers of respective tubes by turning 80° and correct half of apparent error by turning capstan screws each bubble independently.

First adjust vertical cross-hair to lie in plane perpendicular to and level the instrument. Sight the vertical hair on a well- plates, and move telescope up and down. If the point does not ertical cross-hair, loosen screws holding cross-hair ring, and by rew, rotate ring until above condition is fulfilled. Then tighten second part of adjustment as follows: Sight telescope at point *A* clamp vertical axis; invert telescope on its horizontal axis and me elevation as *A*, in line of sight, and about same distance from n clamp, turn horizontally and sight *A* again; clamp horizontal on horizontal axis and if line of sight falls on *B* it is in adjust- *C* in line of sight beside point *B*. Mark or note a point *D* one- veen *C* and *B*, measured from *C*. To adjust, move cross-hair ed, by loosening screw on one side of telescope and tightening has an erecting eye-piece, move ring in direction *D* to *C*; if an e ring in direction *C* to *D*.

rds. Set up and level the transit. Sight on some high point is. Lower the telescope and set point *B* in line of sight about everse telescope, turn instrument 180° horizontally, sight again r telescope until point *B* is visible, and mark point *C* in line of as *B*. If *C* does not fall on *B*, raise or lower adjustable end of pstan-headed screw under it. Bring adjusting screw into posi- n; otherwise the block on which horizontal axis rests may stick . Then tighten capstan screws just enough to avoid looseness

adly out of adjustment, it is better to bring it gradually whole, rather than to attempt to adjust completely one the adjustment of one part will not disturb preceding e not subjected to strains, and instrument will remain

e "peg" adjustment, explained in Art 5).

al circle should read 0° when telescope bubble is in center of screws holding vernier and tap lightly until the zeros coincide. es what is called the INDEX ERROR in measuring vertical angles, in adjustment parallel to bubble tube.

move parallel to line of sight. Adjust line of sight as described very distant objects; then repeat same adjustment using points served in this last test, it indicates that objective slide does not sight. The adjustment is made by moving adjusting screws of to increase the error by one-quarter of observed error. Then sight again on distant points. The adjustments of objective tube, and centering the circles, are usually done by instrument

Transits cost from $75 to $300. They weigh 5 to 15 lb, exc
weigh 7 to 12 lb. Accurate results can be obtained with the ligh
to 4½-in horizontal circle. It is advisable not to use too light a
instruments, on account of wind. Stiff-leg tripods cost $7 to $2
pods, $12 to $35.

5. The Level and its Adjustment

Engineer's level is a telescope to which a delicate sp
parallel to line of sight, so that, when bubble is in center
horizontal. The two common types are the Y- and th
both the telescope is mounted on a vertical axis, about
swing horizontally, and is leveled by 4 leveling screws.

Y-level has its spirit-level attached to telescope, which r
supports, which in turn are fastened to a horizontal bar
vertical axis. The telescope can be taken out of the Y's,
and replaced, when testing bubble for adjustment.

Dumpy-level has its vertical axis, horizontal bar, ar
scope, all cast in one piece, to which spirit-level is atta
level will stand much rougher usage than the Y-level, has
and permits fully as precise work. Practically the only a
has over dumpy-level is that the adjustment of line of sigh
conveniently tested.

Locke hand level is a metal tube with plain glass
small spirit-level on top. When looking through the t
bubble is seen in one-half of tube, being reflected by a pri
tube, the landscape is viewed. When bubble is in center,
where the horizontal line, which appears in center of bubbl
rod (Art 19).

Clinometer is similar to a hand level, except that bub
arm, free to move in a vertical plane. It is used for measuri
telescope along inclined line, moving the arc until bubble
reading angle of inclination.

Adjustments of the Y-level are: (*a*) To make horiz
horizontal and to make line of sight coincide with axis of t
allel to it; (*b*) to make line of sight and axis of bubble
make axis of bubble tube perpendicular to vertical axis.

(*a*) **Line of sight.** First make horizontal cross-hair horizont
level. This is tested after leveling, by sighting on a point and ne
hair appears to remain on the point, as telescope is slowly rotat
Adjustment is made, if necessary, by rotating the cross-hair ri
second adjustment of transit. When this is done, loosen clips
the Ys. Set a fine mark on a wall in the intersection of the cro
vertical axis. Rotate telescope 180° about its own axis. Correct
the screws of cross-hair ring, adjusting first one hair and then the

ect method. Bring the bubble to center of its tube and clamp te telescope in the Ys a few degrees on its horizontal axis; if entire error by the capstan screws at one end of bubble tube. ver a pair of leveling screws and bring bubble into center of tube; urn it end for end, and replace in Ys without jarring the instru- parent error by the vertical adjusting screw of bubble tube.

's. Level the instrument, then bring bubble exactly to middle, crews. Turn telescope 180° on its vertical axis and correct half sting screw of the Y support. Since the bubble is brought to eading of the rod, this last adjustment in no way affects accuracy venience.

lumpy-level are the same in purpose as for Y-level, but ction of instrument, done in a different order and in some cedure. They are: (*a*) to make horizontal cross-hair truly ument is level; (*b*) to make axis of bubble tube perpen- s; (*c*) to make line of sight parallel to axis of bubble.

djusted as described in paragraph *a* above.

evel the instrument and carefully center the bubble over a pair n telescope 180° horizontally and correct half apparent error in screws of level tube.

direct or "peg" method. Select points *A* and *B* 200 ft or el beside *A*, so that when a rod is held on *A* the eye-piece will k through the large end of telescope at the rod and take reading of sight. Point telescope toward *B* and read the rod in usual t bubble is in the middle of tube. Then set up level at *B* and . These observations give two independent determinations of between the two points; the true difference in elevation is the ces. (Same result can be obtained from a single setting of level, ay between *A* and *B*.) Leaving instrument at *B*, set rod at *A*, eight of instrument above *B*, plus or minus the true difference in d *B*. If line of sight is then brought to intersect the rod target, . The bubble being in center of its tube, the line of sight is now et by moving cross-hair ring by its adjusting screws. Example:

	Instrument at Sta *B*
a *A* = 4.243	Rod reading on Sta *B* = 4.618
a *B* = 5.724	Rod reading on Sta *A* = 3.177
d *B* = 1.481	Diff in elev of *B* and *A* = 1.441

es = ½ (1.481 + 1.441) = 1.461, the true difference in elevation. ow 4.618 above the station. Rod reading on Sta *A* should be o give a level sight.

may be applied to line of sight of the Y-level, except that in this as been set at correct elevation to define a level line, the line of arget by the leveling screws and then bubble is brought to mid- screws. This method is also used for adjusting the hand level. its, the adjustment may be made by moving either cross-hair tube. If cross-hair is moved, the adjustment of line of collima- bubble tube is moved, the vertical arc vernier must be adjusted.

of errors, in adjustment of line of sight of bubble tube, or of st be sure that bubble is in center of tube at instant rod is read, foresights are about equal in length.

ned for running long lines of bench levels, are usually equipped rs, an inverting telescope of high power, stadia hairs, very sensi- y a mirror simultaneously with the rod, and a slow-motion screw

s cost from $50 (architect's levels, with horizontal circle) to $150; $200 upward; hand levels about $10.

It is the practice of many surveyors to omit fro
of lines, or angles; this custom can not be too se
practice to letter in some inconspicuous place, p
ence to the notebook containing survey from wh
initials of draftsman. If any leveling has bee
plan, the location and elevation of bench-marks
or plotted on map, preferably both.

On working drawings, and sometimes on
of the survey are drawn, usually as fine, colore
indicated either by very small circles, the ce
points, or by short lines drawn through the po
angles. Triangulation stations are represente

all squares, and other auxiliary stations by circles. The rks is frequently represented by a small cross and figures,

property and the physical features, such as streets or drawn as full black lines. Shore lines are drawn in black should, as a rule, be the heaviest lines on the plan, unless portant feature. Whenever colors are to be used, better obtained with water colors than with bottled inks. Red y unsatisfactory results; in a few years it spreads and leaving the tracing discolored. The following colors are rveyors: burnt sienna, raw sienna, yellow ocher, scarlet pia, cadmium yellow, chrome yellow, gamboge, Hooker's nd indigo. All of these, except gamboge, may be used on danger of running, but if process prints are to be made ssian blue and indigo will not print well. Some colors l prints may be made to do so by adding a little Chinese low to give them body, but not enough to change the ctory way to color a plan is to shade the line or areas by of tracing. Before using the color, rub places where it pencil eraser and after color has been applied rub it down e a uniform shading. On blueprints, for a red line, use for a yellow line, Schoenfeld & Co's light chrome yellow.

ing should, as a rule, read from bottom of plan, that is, hould read from left to right when the plan lies with its

STANFORD LIBRARIES

Reinhardt lettering is rapidly executed, presents a workman-like a used more than any other (Fig 9). For fine lettering, such as Roma pens are suitable. Some draftsmen prefer a little coarser pen, such as and a still coarser pen, Gillott's No 604 EF, will be found suitable for single-stroke work, as for numbering contours or for the smaller dim For still heavier lines, King's No 9 Nonpareil (similar to stub pen) is heavier lines than these, and particularly for executing the Reinhardt patent pens are good; they come in sets of graded size, costing about 9 ing holder. No 6 or 7 Paysant gives about right weight of line fo cloth, while No 4 pen will give a line heavy enough for the main line pens make lines which have somewhat rounded ends, so it is necessar when making the heavier letters, to square up the corners with an as Gillott's No 170. Paysant pens should not be cleaned with a clot taches to slot; they should be cleaned with a small piece of tough pap ball-point pens are used to some extent for single-stroke work, but they use as the Paysant pens.

Title should comprise: brief description of drawing, owner's name, lo scale, date of survey, surveyor's name and address. It should be so most important information is on the most prominent line. The lines centered, arranged in compact form, but not crowded. It is advisable most important or longest line. In other lines, when two words occur arated by a considerable space, first letter right-hand word and th word at same distance from center line of title as is the end right-han of title should conform to size of plan. Never waste time on a fancy read and as most draftsmen are not familiar with such alphabets, t to be poor. Put title in lower right-hand corner of a plan, so that turning up the corner of sheets that lie above it in a drawer. In som set up in type and printed on plan. A rolled plan or profile should b brief title lettered on back, at both ends, so that a title may be visib been rolled in either direction.

Notes are an essential part of most plans; they are usually lett style. Border lines are not necessary on construction drawings, but ings and maps a single firm line, drawn ½ to 1 in from edge of sheet, gi ance. A fine line just inside of a heavier one makes a good border line have a tendency to make border lines too heavy.

Meridian should be represented on all maps as a full arrow, if it b or as a half-arrow, if it represent the magnetic meridian, the half-arr same side as the declination. Make arrows of simple design, and no in size or breadth of lines. It is good practice to show both the true meridian, and to indicate on latter the declination existing at place a Do not let a meridian line cut any other lines of a drawing.

To clean a drawing use sponge eraser, art gum, or dry bread crum gasolene or benzene will remove pencil marks without affecting ink line life out of the tracing and makes it turn yellow with age; it also cause lect dirt more readily. A tracing upon which lettering has been sta cleaned with gasoline.

On working plans requiring accurate scaling, it is advisable to p two long scales at right angles to each other, by which to measure am or swelling of the paper, and to make allowance for it in subsequent from the plan.

Tracings from blueprints or from penciled working drawings can b them on a drawing table having a glass top, and placing table where p fall under it, or else placing electric lights under the table.

Conventional signs are used to represent topography and other A few of the most common are shown in Fig 10. They are used most maps and are produced either in black, as is custom with U S Coast vey, or in color, as on maps of U S Geol Surv. They are executed that straight lines, such as in conventional signs for marshes, railroa are usually ruled. The symbol for marshes should always be parallel

g" the first line outside shore line should be a full line about , drawn as close to the shore line as possible, and should follow larity. Contour lines are almost always drawn in burnt sienna water- Gillott No 303 or a contour pen. Every fifth or tenth contour is slightly wider and a little darker in color. In numbering contours, than are necessary to find the elevation of any contour without di be small figures in burnt sienna. A common mistake is to make co they subordinate the more important features on map.

Sub-aqueous contours are usually represented on hydrographi dash black lines, the shallowest contour having one dot between d tour in depth having two dots between dashes, and so on. In s representing fathoms of water are shown as single dots for first fa a space for second fathom, dots in groups of three for the third, and

LAND SURVEYING

10. Traverse with Compass and Tape

Surveys with compass and tape are adapted only to s sive land, in localities where there is little danger of local m Even serious local attraction may be circumvented if the surv of its occurrence, but when rocks containing magnetic iron ar erally throughout a district, it is difficult, if not impossible, t compass readings. At every station the reverse as well a should be read, to detect local attraction, and, if found, its determined and the erroneous bearings corrected (Art 3). usually read closer than ¼°.

If a compass survey were made of a square lot 1 000 ft on a side, a corresponds to reading bearings to nearest ¼°) in an angle would co of 2.2 ft on a side. In a compass survey, therefore, it is obvious measure the sides closer than to nearest half-foot or foot. Under compass surveys can not be relied upon for an accuracy exceeding 1 erly surveys were often made by compass and chain. In re-running o on transit can be used to aid in finding the physical features whic and a reliable transit and tape survey is then substituted for the ol pass survey (Art 11 and 15).

Magnetic declination is the angle which the needle makes with When necessary to determine this angle accurately, the true merid servation on the sun or on Polaris (Art 13), and then noting its c north end of needle points east of true meridian, it is called an east at a given place the declination changes continually by small amo are called VARIATIONS.

To set off the declination so that the compass will give true beari compass box toward the north. Then, if the declination is east, t to the right by the amount of the declination; if the declination is to the left. Needle readings will then be true bearings.

Isogonic lines are curves connecting points at which the magnet same. Isogonic charts are prepared by the U S Coast and Geodetic on a map the observed declination at numerous magnetic station declinations at intermediate places (see Fig 11). These charts do sults, but are useful for learning approximate declinations. Obse interpolated places are frequently quite different from those stated hence, whenever the magnetic declination is desired with precisio make observations on the true meridian (Art 13).

Changes in declination make it necessary, in re-running old lin bearings by an amount equal to the change in declination which h lines were first run. To determine declination for some past date, r Survey are useful, provided a magnetic station was situated near but it is not safe to rely on records of a magnetic station, even only 5 in a general way. It is always safer to determine the present decli

STANFORD LIBRARIES

ence in elevation by leveling; then compute horizontal distance by paragraph. When much inclined work is to be done, it is advisab 300-ft tape.

(*d*) **Alinement errors** are not likely to be large; lining in the enough for most measurements. If, in measuring 100-ft tape-len out of line, it will introduce an error of only 0.005 ft in that tape-l poor alinement may be computed by the formula: $c - a = h^2 \div$ taped distance, h the offset from the line, and a the correct length. the hypothenuse, a the long leg, and h the short leg of a right triang of a 100-ft tape is on line and the other 0.8 ft off line, the error in th $0.8^2 \div 200 = 0.0032$ ft. Of course there will be a similar error making a total error of 0.0064 ft in the 200 ft. The shorter the taped proportionately is the error due to faulty alinement. This form nearest 0.01 ft, if taped distance is less than 300 ft and offset does taped distance.

(*e*) **Sag.** Measurements frequently have to be taken with tape its ends. It is customary, in this case, to exert a stronger pull than act effect of sag. With a 12-lb pull, on an ordinary 100-ft ribbon at its ends, the increased tape reading due to sag is about 0.01 ft. for any particular tape by the formula: Lengthening due to sag = $($ where w = wt of tape in lb per ft of length, t = pull in lb, l = len supports in ft, and L = total length of tape in ft. The result will nary pull of 10 to 12 lb is given, the correction for sag may be a formula, though this is seldom done.

The most practical and accurate way of eliminating the error due by actual test the amount of pull necessary to apply to a suspended exactly 100 ft apart. Support plumb lines from points previously set 10 ardized tape when supported horizontally throughout, then note pu the suspended tape to be tested so that its end marks will coincide

(*f*) **Temperature correction.** A new tape is of standard leng pull of 12 lb when supported throughout its length. The average co of a steel tape is 0.0000065 per degree F. Thus, a change of 16° of a 100-ft steel tape produces about 0.01 ft error in its length. H are desired, the temperature of the tape must be noted and tempe plied. Small tape-thermometers are made for this purpose; the th in contact with tape, to obtain as closely as possible the temperature then, in sunlight, it is difficult to obtain correct temperature of tap

Cumulative and compensating errors. In all measurements portance to distinguish between errors which tend to balance and late, the latter being far more important. For those which tend to of errors which will probably remain uncompensated, according to me will be the square root of total number of opportunities for error 100-ft tape is 0.02 ft too long a cumulative error of about 1 ft will b a one-mile line. If, on other hand, tape-lengths are not marked cl total error made by this compensating error of 0.05 ft will be only $\sqrt{}$

Angle measured may be the deflection angle, the actual muth angle. The DEFLECTION angle is that between the last c the forward course; the ACTUAL ANGLE measured is usually the angles formed by two diverging lines, although, in case of many surveyors prefer to read consistently either interior The AZIMUTH angle is the angle a course makes with the me sumed) direction measured clockwise, usually from the south deflection angle the telescope has to be inverted, whence a collimation will be introduced into deflection angle; such err sated by turning the angle with the telescope first direct and taking half final reading as correct angle. Deflection R (right) or L (left), according to direction turned.

ecimal places, for every minute of angle and up to 100 units

STANFORD LIBRARIES

The same table can be used for computing horizontal an
sponding to inclined tapings. Nearly every textbook of surv
pocketbook contains a traverse table computed to 15 min of
a traverse table computed to single minutes, a table of log sin

When a traverse does not follow property lines (Fig 12), areas may be computed as simple geometric figures, as in following example:

In Fig 12, ABC is property line and XYZ, 76° 24′ traverse line.

$aA = 25.2 \times \sin 76° 24' = 24.5 \quad bB = 12.7 \times \sin 56° 12' =$

$aX = 25.2 \times \cos 76° 24' = 5.9 \quad bY = 12.7 \times \cos 56° 12' =$

$ab = 5.9 + 207.6 + 7.1 = 220.6 \quad AB = 220.6 + \frac{(24.5 - 10.6)}{2 \times 220.6}$

$$\text{Area } AaBb = 220.6 \times \frac{24.5 + 10.6}{2} = 3$$

$$\text{Area } AXa = \frac{24.5 \times 5.9}{2} =$$

$$\text{Area } BYb = \frac{10.6 \times 7.1}{2} =$$

$$\text{Area } AXYB = 3$$

Another method of wider application, especially in properties, is to compute area from the COORDINATES (see Art 8, this Sec, and Art 9, Sec 18, on *Underground* nates of the corners are computed in ordinary manne distance of each from nearest, or most accessible, traver coordinates are ascertained by method previously descrit consecutively around the tract. Multiply each latitude ence between the following and the preceding longitud tracting the preceding from the following. One-half is the area.

Meandering boundaries, such as brooks, roads, et measuring perpendicular offsets from a traverse line w veniently near the boundary. If curvature of boun offsets are taken at regular intervals, but if it be errati at each point where direction changes. In either ca trapezoids are computed, and their sum added to or sub traverse lines. If offsets be taken at equal intervals, made by one of the following methods.

Trapezoidal rule. Area = $\frac{1}{2} d (h_e + 2 \Sigma h + h_e')$, w val between offsets, h_e and h_e' = end offsets of the Σh = sum of intermediate offsets. This rule assumes straight line between adjacent offsets.

Simpson's one-third rule. Area = $\frac{1}{3} d (h_e + 2 \Sigma h_o$ d = common interval between offsets; h_e and h_e' = first twice the sum of the odd offsets (3d, 5th, 7th, etc); 4 sum of the even offsets (2d, 4th, 6th, etc). To apply an odd number of offsets; if the number is even, comp trapezoid separately. This rule assumes that betwe boundary is a parabola.

In Fig 12 the area of $efZd$ by the trapezoidal rule = $\frac{1}{2} \times$ $+ 11.4 + 122) + 1.6.7] = 1\,293$ sq ft. By Simpson's rule

$+ 11.4) + 12.2] + {}^1/_2 \times 20\,(12.2 + 16.7) = 1\,286$ sq ft. Area
ng area of trapezoid $Bgfe$ and subtracting triangle BgY, giving
is computed by finding area of trapezoid $dZJC$ and subtracting
ı ft. The length of side BC can be found by computing the
y method of Art 10. For example

$$ck = 20 + \frac{(16.7 - 12.2)^2}{2 \times 20} = 20.5 \text{ ft.}$$

Determining the True Meridian

best adapted to the needs of an engineer are: (*a*) by
y transit, the bearing of sun, found from its altitude;
attachment for transit; (*c*) by observing the bearing of
t elongation. The observations consist in measuring
angle between sun or star and the survey line of which
termined; preliminary observations on other factors re-
roblem, such as the altitude of sun or star, the latitude
e usually also necessary.

ns certain times of day are more favorable than others,
ie observations should not be made at all. During sum-
sphere) observations may be made at almost any time
nd between 2 and 5 p m. Observations before 7 a m or

s. An act of Congress specifically provides that corners
d shall be established as proper corners of sections or quarter-
ntended to designate, irrespective of whether or not they were
t place. A further provision is that "the boundary lines actu-

line. In absence of engineer, all this work can be done by foreman. to set grade stakes and offset-line stakes even though engineer h man will then be able to check lines and grades at any time.

To lay off any angle with a tape only, first lay off 100 ft, from vertex *A* of angle, by the 3-4-5 method, using a binations of dimensions for the two legs and hypothenu *CAB*: (3-4-5), (6-8-10), (9-12-15), (12-16-20), (15-20-25), (1 etc. On the perpendicular, measure distance *BC* equal t tangent of angle; angle *CAB* is the required angle.

LEVELING AND CONTOU

18. Profile Leveling

Profile leveling consists in determining elevation of points on a line so that its profile can be plotted and comput The line is first marked off in 100-ft stations, or at shorter The level is set up and a reading, called a backsight (B S or leveling rod held on a BENCH-MARK (B M), which is a point of above mean sea level or any other assumed datum plane determined. The B S is added to elevation of B M, givi ment (H I), or elevation of line of sight above datum pl called foresights (F S or − S), are then read on as many st as can conveniently be seen from instrument, and elevati are found by subtracting F S readings from H I. Rod-re all distinct changes in slope which occur on the line, wh points or not; such intermediate points are located by tape ing) and are recorded as plus stations, as shown in sample

e level to a new position along line, a TURNING POINT levation determined, to be used at the next set-up of v H I. When new H I is found, by a backsight, F S its ahead on the line, after which the elevation of a d so on. The turning point may be a regular station,

ablished before profile levels are run, in which case on those B M's which are passed during profile level- ould if possible be used as T P's. If B M's have been closing check is made on B M nearest end of line of n sample notes. Sometimes the line of levels is made r returning to original B M. By comparing its final t beginning of the work, the error of closure is ascer- ' P readings, although a mistake may still occur in an tion point.

chosen with regard to permanence, and should be nd found. The rod readings on B M's and T P's o one more decimal place than those read for profile. djustment, the distances between level and rod, when ould be about equal for backsight and foresight. The depend upon distance at which rod can be read dis- sion required. Generally, sights should not exceed 300 quired to nearest 0.01 ft, and even at a much shorter air may prevent such precision.

tes may be checked by computing the sum of the s on the first and last bench-mark and on intermediate ence of these sums should check the difference in ele- final bench-marks. It is well to apply this check at level notes. If station points have been marked in , two experienced men can run a line of profile levels ugh to permit a set-up every 600 ft, at rate of about et-ups per hr.

frequently adopted when it is impracticable to complete a ugh new country, where no B M's have been established. single T P, readings are taken on two different T P's, near tion by at least 1 ft. From next set-up, a backsight is taken are computed, which should agree within whatever limit of f work in hand. This is an excellent method; it requires a line of levels by ordinary method described above, and ry new set-up, by detecting mistakes as soon as made.

hing B M's are sometimes run by a precise level (Art 5), or ial precautions with ordinary level. The observations are eliminate the recognized common errors in leveling, which oft ground; (*b*) unequal expansion and contraction of parts s of temperature; (*c*) variable refraction of air near ground; ight and foresight; (*e*) selecting unstable turning points; bubble not in center of tube at instant of reading.

ripod are eliminated by making two readings on backsight set-up, in following manner; first, B S is read, then F S; lastly B S once more; two rodmen are employed. Correct from average B S and F S readings. Errors due to changes y prevented by shortening time between reading of B S and ent should be shielded from sun's rays, and from wind, by . Rapidity is of great advantage in eliminating errors due s due to refraction of air may be partly avoided by using the level high above ground, and by making observations

in the middle of the day, rather than in early morning or late
and foresights are kept nearly equal in length by reading these
hairs; notes should be so kept that they will show at a glance
and B S distances are equal or not. A foot-plate or pin may be
to use for a T P, when a satisfactory point can not be found
instrument. To aid in holding rod plumb various types of spir

In work of precise character, allowance must be made for cur
refraction of atmosphere. These corrections are usually combi
following: for sights of 300 ft, combined correction is 0.002 ft;
1 000 ft, 0.020 ft. The correction is applied by subtracting it fro
but if rod be held equally distant from instrument on F S and
ture and refraction is compensated.

Allowable errors in precise leveling of various surveys are
Survey, $4^{mm} \times \sqrt{\text{kilometers}}$; U S Lake Survey, $10^{mm} \times \sqrt{}$
River Survey, $5^{mm} \times \sqrt{\text{kilometers}}$; U S Geological Survey, 0.
actually reached fall well within these limits. A high grade o
on the Barge Canal Survey of New York with an ordinary Y-le
allowable error of closure was only $0.02^{ft} \times \sqrt{\text{miles}}$. An accura
by a precise leveling instrument can be reached with ordinar
level, but not so economically.

19. Cross-section Leveling

Leveling for cross-sections is required for determi
rial, whether excavated from a cutting or a borrow-pit, or
mining, or occurring in a mine dump. The entire upp
divided by transit and tape into 10- to 100-ft squares (or
to nearest tenth are taken at all corners of squares, and at
points as necessary, in case of irregular ground. Lines ru
are usually lettered, numbers being used for the other s
point F, 8 lies at intersection of line F and line 8; and
(not at a corner) is designated thus $(H + 6, 7 + 2)$, which
from line H toward line I and 2 ft from line 7 toward line
leveling over the same system of cross-section lines, befor
the differences between original and final elevations at
vertical edges of a series of vertical truncated rectang
edges of a borrow-pit, for example, will probably occur
trapezoidal truncated prisms. Let A = area of horizonta
prism, h_1, h_2, h_3, etc = lengths of vertical edges of prism, a

For truncated triangular prism, $V = A \times (h_1 + h_2 + h_3)$

For truncated rectangular prism, $V = A \times (h_1 + h_2 + h_3 +$

When additional elevations are taken at intermediate
prism should be divided into triangular prisms; the addi
forms the vertical edge at one corner of each triangular
rectangular prisms occur, having same area of cross-secti
of volume may be simplified thus: Volume of assembly of
prisms $= A\ (p_1 + 2\ p_2 + 3\ p_3 + 4\ p_4) \div 4$, in which p_1 = sum
one prism, p_2 = sum of heights common to two prisms, p_3 =
to three, p_4 = sum of those common to four prisms.

If several intermediate elevations have been ascertained, it is
from original surface down to some plane below final surface.
putations for volume between final surface and the same plane.
these two volumes will give required volume.

Road cross-sections, as a basis for estimating quan
railroad or highway construction, are taken by a met
from the above. From plan of proposed road its aline

ter line (Art 18), and is subsequently plotted. On is drawn, which corresponds either to sub-grade or to Roads are usually first finished to sub-grade, which is ce by an amount equal to thickness of road covering, r ballast of a railroad. The width of base of road and are known. For ordinary earth the slope is usually ertical, called "a slope of 1.5 to 1."

he engineer sets grade stakes at every full station, or d slope stakes at both sides, where finished slope will d. All three stakes are marked, stating amount of de at center point, or, in case of slope stakes, stating base of the road to surface of ground at these points. not only at every full station, but at every distinct er line, and also where surface on either side of center ate section properly to represent the volume included Cross-sections are taken perpendicular to center line rves.

he center, set up the level and find the H I to nearest 0.01 ion or bench-mark of which the elevation is known. From vation at given station. The H I minus grade elevation e, which is computed to nearest 0.1 ft. Take a rod-reading he difference between rod-reading for grade and surface rod- at point. It is customary to record cuts as + and fills −. ned by adding the cut to grade elevation, or by subtracting, e is driven on center line and marked with cut or fill, thus:

he points where side slopes meet surface. These stakes are e the ground lies above or below base of section; it is called , but, strictly speaking, there is no cut or fill at slope stakes. is found by trial as follows: In the case of a cut, estimate ermined, and from slope of surface, what the probable side rom center stake to a point on side slope having this cut pe). Make this computation roughly, measure out this nd take a rod-reading at that point. The rod-reading for base of section) minus this surface rod-reading gives cut at act distance out from center stake to a point on side slope mputed distance equals measured distance from center to ct; if not, a second trial must be made by holding rod on operation; the difference between measured and calculated re to hold the rod for second trial. When correct point is d distance equals calculated distance, the stake is marked distance this point lies above the base. The depth of cut, slope stakes, are entered in notes. The same process is re- er side of center. Rod-readings are taken at intermediate needed to define shape of surface; their positions are located center stake, while the cuts at these points are the differ- r grade and surface rod-readings. The field notes of a sec- 30-ft base and slopes 1.5 to 1, which required 4 readings to would be entered thus: $\frac{21.3}{-4.2}$ $\frac{14.7}{-6.1}$ -3.2 $\frac{17.1}{-1.4}$.

ion may be computed by dividing it into triangles, or cross- their areas determined by planimeter (Art 6). By the end tween sections A_1 and $A_2 = \frac{1}{2}(A_1 + A_2) \times$ distance be-

ns, canals, and other engineering structures are begun t right angles to line of structure, at intervals of 10 to nditions, and extending far enough on either side to

include the possible location of structure. These cro
ing the surface, are plotted for each station, and on
cross-sections of proposed completed structure at the
gives a complete record of conditions before work is st
a continuous graphic record of work may be kept fro
of different colored lines on the various cross-sections.

20. Barometric Leveling

The barometer is based upon the principle that
function of elevation above sea level, a change of 1 in
sponding to a change of about 900 ft in elevation. A
also with changes in temperature and humidity, whe
measuring differences of altitude with a barometer, to
and make proper allowance for them. Both mercuri
are used in surveying, but the latter, on account of i
generally employed.

Barometric leveling is used for reconnoissance, or
for a small-scale map. With an aneroid, results as clos
but not without repeating observations and using in
The error in elevations determined by barometer i
whence the percentage error is smaller for large dif
for small differences. The barometer does not give
difference between two readings will be a function of
the two points, provided atmospheric conditions ha
affect readings.

The aneroid barometer has two scales, the inner o
of mercury and the outer one to feet of altitude, the
being, in most instruments, at 31 in on mercury scale.
be movable with respect to inner scale, for the numbe
sponding to 1 in of mercury varies in different parts o
"compensated" are supposed to be so adjusted that
the instrument will not affect readings. The instr
carefully, to avoid disturbing its delicate mechanism
tap the case lightly to make sure that the instrument
changed pressure; it should then stand a few minutes
true reading. It should not be heated by the sun
be held in either vertical or horizontal position wh
readings in these two positions are different it shoul
at all stations. As accurate results may be obtained
aneroids.

The best method of determining elevations by baro
ments, one being kept at a fixed station of known ele
intervals to indicate changes in atmospheric pressure,
to the various points of which elevations are to be de
in elevation shown by the traveling barometer, corr
cated by fixed barometer, will be the true difference
should be noted whenever the field barometer is read
correction as indicated by fixed barometer. The air
be noted whenever barometer is read. If only one
should be read at initial station and again at same st
other observations, atmospheric changes during the i
from difference between first and last readings.

permission, from the "American Civil Engineers' Pocket Book."

Calculating the altitude. The Laplace formula for calculati
tion (neglecting small corrections) is:

$$D = 60\,158.6\,(\log h - \log H)\left\{1 + (t_a' + t_a - 64^\circ)\right.$$

where D = difference in elevation in feet; h = height of mercu
inches; H = height of mercury at upper station in inches; t_a' a
temperatures, Fah. The temperature correction is the only one n
aneroid; it is often large. In case a mercurial barometer is used,
at upper station reduced to temperature of mercury at lower sta

$$H = h'\left\{1 + 0.00008967\,(t_m - t_m')\right\}.$$

where t_m = temperature of mercury at lower station and t_m' = t
at upper station. Table on preceding page, condensed from that
the Laplace formula; it gives the preceding values of log height × 60 158.6

Example using one aneroid barometer to find difference in ele
set River and Blue Hill:

Station	Time	Inches, b
Neponset River	1.00 p m	30.39
Blue Hill	1.45 "	27.73
Neponset River	2.25 "	30.39

Time going up = 40 min; total time = 85 min. Difference in
lower station = 0.005. Probable reading at Neponset River
− (45 ÷ 85 × 0.005) = 30.392 in.

From barometric table	30.392 in	= 29 042 f
	29.730 "	= 28 466
	Difference	= 576 f
Temp corr = $576\left[\left\{\frac{1}{2}(53+42)+47\right\}-64\right]\div 900$		= + 20
Difference in elevation		= 596 f

Boiling-point thermometer. Great differences in elevation
roughly by means of the boiling-point thermometer. Such meas
the fact that the boiling point of water diminishes as atmosphe
and therefore the temperature of boiling point is a function of th
ment. The observation consists in noting temperature of boiling
eter placed in a boiler made especially for the purpose. The app
sea level may then be found by referring to the following table.

Boiling point (Fah)	Alt in feet above sea level	Boiling point (Fah)	Al abov
190	11 720	208	
195	8 950	209	
200	6 250	210	
202	5 185	211	
204	4 130	212	
206	3 085	213	

This table is taken from Wilson's *Topographic Su*

21. Contours

A contour line is the intersection of a level surface
ground. The shore line of a lake is a contour, and if lake
the new shore line would be of different shape and would

. Contours, therefore, connecting points of same ele-
epresent the slope of ground, and provide a means for
nap the approximate elevation of any point. They are
mber of feet above the datum and at regular intervals,
; the number marked on contour is its elevation above

ontours are: (*a*) All points on any contour have same
ontour closes on itself, either within or beyond limits
which closes within limits of map encloses either a
In depressions will usually be found a pond or a lake;
ater the contours are usually marked in some way to

se lines on a map, mark the elevations, and sketch the

it should be borne in mind that they can be interpo-
and that the data necessary to obtain in the field are
haracteristic points on profiles, such as tops of knolls,
rofiles of ridges and of streams. Contours are usually
d bottom of a natural eroded slope (where no wave
n middle Where contour interval is small, and much
und may be cross-sectioned (Art 19) and from elevations
s may be sketched; or contours may be actually traced
ld by stadia; in this case the rodman moves up or down
eading shows that the foot of his rod is on a contour.
ien located by distance and azimuth (Art 23).

is often used to determine elevation of additional points,
on transit line as B M's, as follows: First measure distance
eye, which may be, say, 5.2 ft. Then, from a reading of the
vn elevation the height of levelman's eye is determined. The
n uphill or down until rod-reading is such as will correspond
ntour; the point thus found is located by tape or by pacing.
l on a side-hill, the levelman then moves uphill past the located
nds, until he reads the contour interval plus 5.2 on the rod;
ontour, which is then located by taping. The levelman re-
rodman travels uphill until levelman reads on rod 5.2 minus
s now resting on the next higher contour. In going downhill,
r while levelman backs down the hill until he reads 5.2 minus
he will be standing on contour next below rodman; the rod-
and backs down the hill until the rod-reading is 5.2 plus the
next lower contour. Hand-leveling is not accurate enough
bout 400 ft away from a B M. If several profiles be run along
dotted on map, and then a few necessary side shots be located
an then be sketched. The best method of locating contours
methods (Art 22 to 25).

TOPOGRAPHIC AND RAILROAD

22. Stadia Method

The stadia method measures distances by observing, through instrument, the space on a graduated rod intercepted betwe called STADIA HAIRS, which are spaced equal distances above an zontal cross-hair. When rod is held at different distances from spaces on the rod will be included between the stadia hairs. T measuring distances while filling in details of topographic and h has the great advantages that the intervening country does not inaccessible distances, as across water surfaces, can be measure ment are compensating rather than cumulative, while its accura kinds of work, even for determination of area in some cases s part in 500 may be attained with the stadia. STADIA RODS ar illustrations indicating method of reading them.

Fundamental principle of the stadia is the geometric theorem homologous sides are proportional. The common vertex of the tri the center of the transit, but a point in front of telescope obje

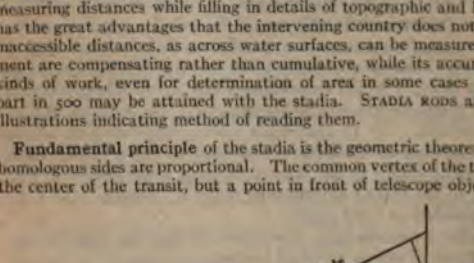

Fig 25 *a*

and 2 ft for plane-table alidades. The other function $(F \div i)$ is customary to space stadia hairs so that $F \div i = 100$, the eq ments reduces to: *distance* $= 100\ s + 1$. Every 0.01 ft on rod t distance of 1 ft.

Inclined sights. It is necessary always to hold rod verti being taken. When line of sight is inclined, the distance inte represents a distance greater even than the inclined distance t tance is greater also than horizontal distance. All inclined re reduced to the horizontal, and if difference in elevation betwee rod station is desired the vertical distance also must be compute By trigonometry, making one slight assumption, it may be sh

$$\textit{Vertical Distance} = (F \div i)\, s \times \tfrac{1}{2} \sin 2\alpha + (F$$
$$\textit{Horizontal Distance} = (F \div i)\, s \times \cos^2 \alpha + (F + c)$$

For the ordinary conditions (when $F \div i = 100$, and $F + c =$ proximations that $\sin \alpha = \frac{1}{2} \sin 2\alpha$, and that $\cos \alpha = \cos^2 \alpha$, formulas, which assumptions are nearly true for small angles,

$$\textit{Vertical Distance} = (100 \times \textit{rod interval} + 1)\, \tfrac{1}{2} s$$
$$\textit{Horizontal Distance} = (100 \times \textit{rod interval} + 1) \cos^2$$

These are the formulas used for ordinary stadia work. The red be best accomplished, however, by use of tables, diagrams, or which are based upon these formulas.

23. Stadia Fieldwork

by (*a*) azimuth, (*b*) distance, and (*c*) angle of elevation
ations are not required, the vertical angle is read only to
hat is close enough for determining horizontal distance;

found by this method should be checked, if possible, by resection line
of which the positions are known to be correct.

26. Triangulation and Trigonometric Level

Triangulation consists in locating certain points by obser
starting from a base-line which has been accurately measured
often used as a control for a topographic or hydrographic surv
tion system comprises a series of triangles, the corners of whic
ing stations or points which it is desired to locate. In this sy
the length of one side of some triangle must be measured; the
in each triangle be observed, lengths of all other lines in the sy
culated by trigonometry. Three types of triangulation syste
nized: First, a series of approximately equilateral triangles;
central polygons, for example, a row of hexagons each having a
third, a series of quadrilaterals with both diagonals drawn.
is the cheapest when it is desired to extend survey along a
surveying a river. It has the disadvantage of having but few
few geometric conditions which must be satisfied by the mea
second system is adapted to surveying an area of greater wid
The third is the most accurate, because it has the greatest n
No attempt will here be made to describe the precise work
U S Coast Survey in mapping large areas, the following note
such work as the mapping of a few square miles.

Fieldwork consists in first making a reconnoissance of the
suitable triangulation points with due regard to shape of the
should be as nearly equilateral as possible, choosing a favorabl
base-line to be measured by tape, and ascertaining that the
visible each from the others.

Base-line should be located on fairly even ground, for conve
ment, and its position should be such as to admit of accurate connect
gulation system. After clearing line of obstructions, stakes are line
tape length apart. The grade of each tape length is determined by
the actual measurement of each tape length the intermediate support
vertically and horizontally, proper tension is applied with a spring
perature is read on two or more thermometers attached to the tape.
the ends of tape length are scratched on strips of metal tacked to
least two complete measurements of the entire base should be made.
For complete description of methods used in base measurement, see
intendent of U S Coast and Geodetic Survey for 1907 (p 105) and 191

Angle measurements. The transit is set up at each end of base-
carefully measured by repetition (Art 11), to the signals erected at

STANFORD LIBRARIES

tended to be connected directly with the base. The transit is then
s points of triangulation system, and the necessary angles are meas-
of every line in system can be computed, and as many as desired
omputation through different triangles.

ngulation points are frequently made of a 4 by 4-in pole supported by
e are tacked black and white cloth bands of definite width, or flags.
supported 7 or 8 ft above the ground, so that theodolite may be set
hen measuring angles. Tripod signals may also be made of young
smaller ones the pole usually rests on the station point; this neces-
ie entire signal when angles are measured at that station. Where it
a high signal, on account of woods, a tall mast may be made of 2 or
ther, and braced by wire guys. In all cases it is advisable to tack
and to that part of the pole which is *vertically over the station*, so
ay always be made on that particular point.

leveling consists in computing difference in elevation of two
s of horizontal distance and vertical angle between them; it
l with triangulation work, the vertical angles being measured
rizontal angles. A vertical angle is measured to some definite
e height of which above station was determined when signal
height of instrument above its own station should also be
orded. In very precise work, angles are measured with a
cle instrument. In less precise work, an ordinary theodo-
: of which reads to 30 sec or to 20 sec, may be used, but with
nly single readings can be made; in which case the best re-
by averaging several independent readings, half of which are
pe direct and the other half with telescope inverted. In
x correction, or reading of vertical arc when telescope is level,

ty in obtaining accurate results by trigonometric leveling is
the coefficient of refraction of the air. This varies with
re, and atmospheric pressure, and the only way its effect
s by taking simultaneous observations between two stations.

ne station. Multiply horizontal distance by tangent of vertical
gle correction for curvature and refraction by the formula: $h = K^2$
distance between stations in miles, and h is correction in feet. If
ft, then $h = 0.02\ K^2$ (nearly). This correction is applied to increase
if vertical angle is positive, or to decrease it if angle is negative.

neous observations can be made, $h_1 - h_2 = K \tan \frac{1}{2}(\alpha_2 - \alpha_1)$
$+ K^2 + 12 R^2\}$, where $h_1 - h_2$ = difference in elevation of stations
e earth subtended between plumb lines through the two stations

or this work sometimes consists of a transit, so constructed
elescope can be removed and a camera mounted in their

place, so that azimuth angles can be measured, or laid off, circle. The instrument is leveled and horizontal angles be defined points are measured while telescope is on transit; w substituted, the same angles are laid off on the circle and made. Such instruments cost about $400.

Notches on the 4 sides of the camera opening yield corres edges of every picture; lines are then drawn across photograp 4 points. The vertical line is known as the PRINCIPAL an HORIZONTAL line; their intersection is called the PRINCIPAL P

If photograph be held at distance f in front of the eye, and normal a, b, and c on the picture will appear to cover corresponding points A, scape. The photograph, when held in this position, thus gives a n between various points in the view; a fact utilized in plotting.

To plot map, first locate positions of camera stations X and Y station draw a circle of radius f, and a radial line representing direc was pointed when photograph was taken, as Xm and Yn. Line op photograph, tangent to line, and qr represents Y, its principal line pa plot point a, first meas the distance from a to plot that distance on l larly, the distance na' other photograph and The plotted position of tion of Xa' and Ya'', o ner are plotted as ma

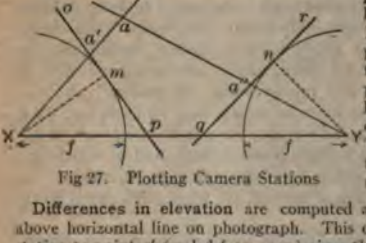

Fig 27. Plotting Camera Stations

Differences in elevation are computed as follows: Scale the above horizontal line on photograph. This distance divided by d station to point a' (scaled from map) gives the natural tangent of depression. The actual horizontal distance Xa is then scaled from has been plotted, and is multiplied by tangent of vertical angle, to vation between camera station and point a; or it can be found gra map are now sketched from a study of the photograph, after chara been plotted.

28. Hydrographic Surveying

Hydrographic surveying is usually applied to the deter of bottom of a body of water, sometimes including a determi of material composing the bottom. It is customary first to shore, by triangulation or traverse, to which the hydrograp referred, then to measure (usually from a boat) the depth o points, and determine position of these points. Besides or tape outfit, a sounding-pole (or lead-line in deep water) and sary equipment will be required. In tidal waters, and in level changes rapidly, a tide gage should be installed. Soundi to self-reading rods, graduated to 0.1 ft; a shoe is sometimes end, provided with a cup-shaped cavity which, when smea soap, brings up samples of material from the bottom. The l or a hemp or cotton line, to which is attached a lead weig chain is satisfactory, having cloth tags of various colors for f there is little current, a 6- to 10-lb weight suffices for depths

Locating soundings. There are 6 general methods: (*a*) on a range line, at uniform speed, and soundings are located (*b*) Boat is rowed on a range line, while positions of soundin a transit reading from shore, or by an angle taken with

in best available map of the country. For this purpose the articularly valuable, because they give elevations as well as be obtained for 10¢ each from office of U S Geological Sur- on these maps, a paper reconnoissance can be made in the

office, probable grades and alinement can be studied, and a very good gener
without going into the field. Such paper reconnoissance ought always to be
examination of the ground, to determine character of excavation, bridge cros
important details. Large portions of the country have not yet been surve
Geol Surv, and it is not uncommon for an engineer to find himself without
him. In this case he should travel over the most favorable routes, obtaini
pacing or stadia, and elevations by aneroid barometer and hand-level; these
porated into a rough reconnoissance map. He should take into consideratio
cost of road, but also that of maintaining and operating it, noting, therefore,
ture, length of line, earthwork, character of soil, bridging, tunneling, and c

A ridge location usually has advantage of affording good drainage. A
usually permits better grades, but almost always requires more bridges an
is more subject to washouts. A sidehill location, where slope is not too irr
has advantage that proposed line can be placed at any desired grade. O
tainous countries, operative grades can not be obtained, even in bott
valleys; the road must then be purposely lengthened by entering lateral
looping upon itself. In routes which cross drainage systems, it is impor
mine the lowest passes and use these points as governing the location; in
is advisable either to tunnel at the pass or to operate for a short distanc
grade, with a helper engine or by breaking the train in halves. In such l
is almost always of much greater importance than length of line or amount
although due regard must be given to sharpness of curvature, for reasons

Preliminary survey is a topographic survey of the belt in wh
location of the railroad will lie; it will first be run as a transit and
to be used as a back-bone for topographic details. An accurate
survey aids greatly in the location survey which is to follow. I
measured usually to 0.1 ft, and deflection angles to nearest minute;
distances are read by stadia. This map is usually plotted on a sc
400 ft to 1 in. A preliminary party in open country will cover
miles per day. The level party following the transit party establ
marks and determines the profile along preliminary line.

Topographic details are sketched to scale on cross-section paper in th
elevations given by level party as bench-marks; a stadia survey or a plane
adapted to this work in open country; in wooded country a hand-level is
A 5-ft contour interval is customary. The preliminary map and topogr
should be plotted at close of each day, from which the locating engineer w
day to day whether to push ahead on the line adopted, or to retract and
different ground. Not infrequently preliminary surveys of more than one l
The kinds of material encountered along the route are noted and the cha
bridge crossings. Upon the preliminary plan the locating engineer can dra
line, composed of straight lines and circular curves, and from the contour
proposed location line can be plotted. From a study of the different line
the engineer will determine a final line, which will be drafted upon preli
and run out by the party as center line of the location.

Location line, as laid out on the preliminary map, will be so choser
sect controlling points, such as bridge sites and passes, and to minimize
of earthwork. Due regard is given to grades and characteristics of th
On curves, the rate of grade should be flattened about 0.04% per deg
ture, to neutralize additional train resistance; called CURVE COMPE

It is good practice to lay out grade line for a branch connection as nearly
ticable for about a train length from its junction with main line. Similarly
should be given for short distance in vicinity of a mine; this permits locom
its train before climbing up-grade, or, if grade is down, it prevents loaded c
ning away. These flat grades are advisable, from an operating standpoin
obtain them, it is necessary to steepen other grades. Wherever the line i
more than 500 ft long, it is advisable to let this occur on grades as steep as
vide drainage. In passing through low flat land, the line should be built a f

Deflection angle is the most common method for locating simple curve a curve by this method, set transit at the T C, the vernier reading 0°, a (Fig 29). Lay off deflection angles AB 1 and measure chord B 1, thus lo Angle AB 1 = ½ α_1, and $\alpha_1 = D \times B$ 1 ÷ 100. Leaving lower plate of tr loosen upper motion, lay off AB measure chord 1–2, and so on, sett and checking at end of curve on The total deflection angle to any is evidently half the central angle and that point; where stations ar the deflections increase by ½ D fo sive station.

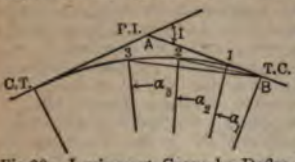

Fig 29. Laying out Curve by Deflection Angles

Deflection angle for any sub-c 200 (in degrees) = $c \times 0.3 \times D$ (in D is in degrees).

Example. Find deflection angles of a 6° curve connecting T C 8 + 42 + 73-4, the curve being to right.

$58.3 \times 0.3 \times 6 = 105' =$ 1° 45′ to Sta 9
1° 45′ + 3° = 4° 45′ " " 10
4° 45′ + 3° = 7° 45′ " " 11
7° 45′ + 3° = 10° 45′ " " 12
$73\text{-}4 \times 0.3 \times 6 = 132' =$ 2° 12′
12° 57′ to Sta 12 + 73-4

C T 12 + 73-4 − T C 8 + 41.7 = 431.7 = Length of cu
4.317 × 6° = 25°.902 = 25°54′ = I; and 12°57′ = ½

This checks deflection angle from T C to C T. As a rule deflection ang computed to nearest half-minute.

Main-line locomotives, as a rule, are limited to curves of 16° to 20 upon their length of wheel base and number of wheels having flanges senger coaches will not go around a 20° curve unless the truck swivel-c connected. A 4-wheel switching engine will, as a rule, go safely arou 75-ft radius, and a 6-wheel switching engine around one of 90- to 1 depending upon its design. A single box car can be pulled around a radius, and two box cars around curves of 80 to 100-ft radius if a spe coupler be used between cars, and between tender and locomotive. about 140-ft radius the corners of freight cars are liable to collide if th has the ordinary M C B coupler. On all especially sharp curves the ga properly widened, the rails braced, guard rails set, and curvature ma form. STANDARD GAGE is 4 ft 8.5 in. The widening of gage may be ¾ in on sharpest curves. It is advisable to lay guard rails on all curves 14°. It is of importance to lay out a branch line so that a main-lin can run over it; this can be done if the curves are of not less than 3

Cost of branch R R lines varies with amount of earthwork a required. Under ordinary conditions, where cuts and fills average total cost per mile of single track branch line is about $10 000. tracks in place will cost from $1.20 to $2.00 per linear ft of track estimate assumes ties at 65¢ each, that gravel ballast is obtaina few miles, that ballast is 12 in deep under ties, and that relayer ra costing $20 per ton (that is, rails previously used on main-line track but still serviceable for branch track):

	Cost pe
Gravel ballast @ $0.65 per cu yd in place	
Ties, 24 in c-c, @ 65¢ each	
Relayer 75-lb rails, @ $20 per ton	
Rail splices and bolts, 5¢; spikes, 4¢

Introductory. An underground survey is based on precisely the same one on the surface. The methods of reading angles and measuring distan puting azimuths, bearings, latitudes and departures, coördinates, and elev plotting the results, are alike in all essentials; for these principles, refere made to the preceding section. In their practical details, however, a num ences are introduced by certain peculiar conditions under which a mine sur conducted. These conditions are: 1. Working in the dark requires that b to be sighted and the cross-hairs of a telescope must be illuminated. 2. constricted places, and in passages through which traffic must not be inter requires the use of special devices for mounting the instrument. 3. Stat placed in the roof, when possible, to assure their permanence and visibility inclined sights are more prevalent, requiring that a transit shall be adjustment; with very steep sights, an auxiliary telescope is required, inv rection in the reading of angles. 5. A higher degree of accuracy is usually in ordinary land surveying; in this respect, mine surveying is comparable wit of bridge piers or the boundaries of city real estate. This is because, in m portant problems in mine engineering, aside from mere mapping, an error time and money in the subsequent mining operations. Furthermore, happens that a complete circuit can not be made, whereby the error of cl determined and distributed, or a mistake located and corrected; hence ca refined methods is the only assurance of accuracy. 6. Shaft-plumbing problem, peculiar to underground surveying,

1. Stations

ion of the points to be occupied as stations will facilitate
ns, and extra time devoted to this end is well spent. In
where the workings are regular and long sights possible,
he head chain man to select and put in the stations as the
in most metal mines, especially if an entire new survey is
visable to select the points throughout the whole workings
instrumental work. Three men can do this to best ad-
ections of workings the point should allow sights to be
ns; intermediate points should allow the sights to be as
rdinarily, little advantage is gained by attempting to set
ine, with the idea of reducing office calculations; an excep-
nt may be made in the case of a series of chutes along a
ch of which it is proposed to run short, independent sur-
for this purpose can be set in line with sufficient accuracy
drift. In dodging corners in a crooked passage, a longer
be obtained by making an abnormally low or high set-up,
le temporary discomfort to the instrument man; this is
inclined workings, where projections in roof and floor,
ls, have to be dodged. In passages where traffic is heavy,
so low that a projecting spad would be in the way, stations
vall. In setting a station at which the side auxiliary tele-
(Art 4), an additional allowance of space must be left
he line of sight.

In important surveys, and where permanency is desired,
ixed in the rock roof of the workings. For temporary
be fastened to timbers, or may be set on the ties or rails
floor; but in such cases, permanent roof stations should be
ntervals. This is best done by drilling a hole in the roof,
plug, and driving a spad into the plug. To save labor of
uld be as small as possible; there is no advantage in having

ordinary plumb-bob. Instead of a lamp a candle sconce havi screen is often used.

Of cross-hairs. With short sights against an illuminated with long sights against an acetylene lamp, no special illuminat hairs is necessary. When illumination is required, the oblique supplied by all instrument makers, for attachment to the end is entirely satisfactory. A similar reflector can be improvis visiting card and putting it into the front of the ordinary tran

Of verniers, etc. Instrument readings are generally mad form of light the surveyor carries. Magnetic readings must cand'e, or a copper lamp. Electric storage-battery lamps ar reading verniers. Instrument makers sell a combination el magnifying lens for this purpose. If a plain magnifying lens i have a metal case, not celluloid. For all-round use nothing exc lamp, with parabolic reflector. The makers supply a specia which points the flame upwards, so that it is less likely to injur held close to it. The objection of some surveyors that an especially of the larger sizes, does not leave the hands free to op ment, can be overcome by hooking the lamp on a tripod leg, or or collar of the coat, or on a strap around the neck.

3. Transit Mountings, Plumb-bobs, Etc.

Tripods. For underground work tripods having extens necessity. The clamps and rings should be extra loose, to al of the extension piece in the mine dampness. The steel po should be sharpened from tin working on inclined rock floors. allowing the center of a transit fortably within 30 in of the flo convenient under low roof. set-ups, or in awkward place bered stope or a shaft botto pod (Fig 3) can be set on a plank.

Fig 3. Trivet

Bracket. In timbered drifts, where a tripod would be in th and in constricted places where no tripod can be set, the bracket is useful. A sound and firm timber must be selected; a hole is bored horizontally at the proper spot, and the bracket is screwed snugly into place with a steel bar fitting through the hole provided for that purpose. The screw-plate is then leveled roughly by the clamp joint, the transit is screwed on, leveled accurately, and brought exactly under the point by the sliding head.

Fig 4. Transit

Plumb-bobs. In draughty workings heavy bobs, weighing 14 to 18 oz, should be used. The instrument bob should preferably shown at *a*, Fig 5, with a fine point. For sighting bobs t

(*c*) Vertical verniers to read 0° when telescope axis truly horizontal; this is particularly important because of ghts. A sensitive striding level attached to this axis is a valuable es.

The practice of transferring a roof point to the floor, this point, should be condemned. It introduces inaccur- is no easier than setting under the roof point, as a little e with the latter method will prove. Hang the plumb- ills under the center of the spad, not tangent to one side verniers at 0°. Move the tripod under the plumb-bob by the legs, keeping the head of the tripod fairly level and under the point, regardless of the transit itself. Level ljust the plumb-bob until its point almost touches the elescope, and observe the direction and distance by which Loosen all leveling screws by the same amount, and tripod head, without turning it, until the points coincide. level accurately by means of the long bubble and striding sary to repeat the shifting operation once more.

sing. The manipulation of the transit, and the several have been fully described in the preceding section, nty can be avoided by adopting an invariable rule for the of all angles, whether exterior, interior, acute, or obtuse. t angles be read always clockwise, sighting first at the bly recording in the same manner as read. The record 178° can then have but one meaning, namely, that the on 9, backsighted on station 8, and turned 178° to the deflections or azimuths are read, instead of angles, it is orded reading refers to the course indicated by the last rce of circumstances it is more convenient to read an , in the direction opposite to that in which the traverse e angle should nevertheless be recorded as read; the ould be designated plus or minus, as read, leaving it to pplementary angles and transpose signs into conformity se.

This is the method most commonly employed in under- ly a medium degree of accuracy. For the actual process s *advantages* are: (*a*) More rapid than other methods. lculation and plotting, especially when numerous side points off the traverse. (*c*) An error of closure in the scovered as soon as the final course is read. Its *draw-* uracy of any one angle reading is limited to 30 min. kept in perfect adjustment by daily inspection, because umulative. (This objection can be overcome by taking lescope alternately direct and inverted, although, by so e distorted by the amount of the instrumental error.) error is discovered, there is no sure way to ascertain or occurred at one set-up; nor, if the latter, at which hecking a single error at a station is the only argument ings, but under *modern conditions* the compass is more *the observer.* *Extreme carefulness* on his part is the *y.*

Deflection traverse. The vernier being set at 0°, at the back station with the lower motion; then ere motion to point at the station ahead. Record the defl ing the lower motion, turn the instrument back to t Invert telescope, and turn off the deflection again. divide by 2, and call this the correct deflection angle mental errors are compensated, and the possible error is reduced to 15 sec. The mistake most likely to occ method is to confuse right and left on very small d graduated in clockwise direction only, and deflections read, the mistake is less likely to happen.

Angle traverse. By the system of repetition angle reading can be reduced to almost any desired traversing two sets of four repetitions will give the cor greater than can be attained in the taping of distanc Method of repeating angles is described in Sec 17, Art on preceding page for recording angles. The only di regular and extensive work is that it adds to the bur which, however, is often warranted by the higher deg

Fig 8. Lamp Targets

Three-tripod method requires the use of specially instruments, a transit, and two lamps or targets. The ver inclosed by a thimble which fits into a socket in the levelin clamp and a spring plug engaging a groove on the thimble fit into the same socket, and the length of the lamp standa

STANFORD LIBRARIES

of the wick tube, is at the same height above the leveling head as sit. The lamp standard carries a pair of level bubbles. The best lard oil should be burned if the bull's-eye lantern supplied by the small-sized acetylene lamp with a special surveyor's tip (Art 2) is s bulky, and more satisfactory in every way. It can be held in ut threaded on a short stud soldered to the bottom of the carbide The method of traversing is as follows: While the transit is being sets one lamp under the forward station and one under the back the target, or of the wick, being set exactly under the point of the

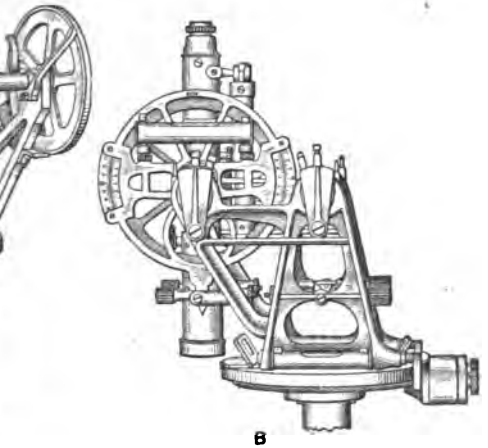
If the backsight, for example, is steeply e instrument station, and the foresight downward, it is more telescope for the backsight and read the horizontal deflection, ngle, which would involve adjustment of the prism for each

ve. Sight the telescope on a sharp point, and bisect accurately Attach the prism to the side objective, and bring the interior the former by its tangent screw until the point is again bisected. e read directly. Horizontal angles are corrected, or corrections ely the same manner as with an auxiliary telescope.

Several manufacturers make a transit on which the main ently, or may be temporarily, offset from its usual position, to vertically, if need be. One of the former type, made by Young nd one of the latter type, made by C. L. Berger & Sons, at *B*,



ig 16. Two Types of Eccentric Transits

transferable telescope precautions must be taken to assure the ontal axis, by means of a striding level; the coincidence of the e with the central position of the long bubble should also be l angles are to be read by duplication. Both horizontal and directly. The instrument should be centered under the station, should be taped to the eccentric axis; vertical distances are then computation, and the only correction to be applied relates to which must be increased by the amount of eccentricity of the city.

5. Measuring Vertical Distances

In most metal mines, and in many coal mines, vertical distances, a obtained by computation on the basis of vertical angles; the leveling m used, but even then the leveling is commonly done with a transit. Wh has to be done, it is advisable to use a Y-level, because in important respective elevations of various points should be known with no less a horizontal coordinates.

Computation from vertical angles. Angles below the hori negative, and those above horizontal are called positive. In F taped distance from the center of instrument at A, to the point α is the vertical angle, with its appropriate sign carefully noted the vertical distance is: $v = l \sin \alpha$, and takes the same sign a of instrument, $H.I$, or i, is the vertical distance from the cent up to the bottom of the spad, and the height of sight, $H.S$, o sponding distance from the point sighted at up to its spad. T elevation between the two spads, d, is thus the algebraic sum: That is, when the vertical angle is positive, add v to s and s

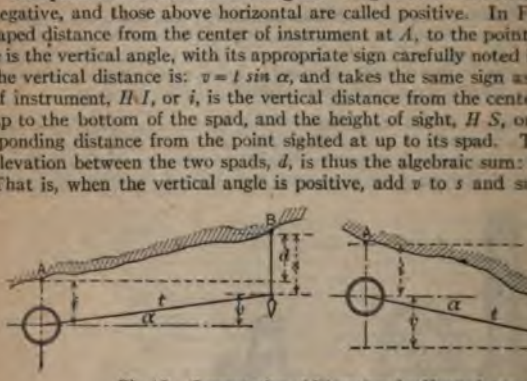


Fig 17. Computation of Elevations by Vertical Angl

the angle is negative, add v to i, and subtract s. Sometimes will be read, while the actual difference in elevation is positive, but if the algebraic signs are kept firmly in mind, no confusion wil ing the elevation of A, the elevation of B is computed by the El B = El $A - i \pm v + s$. In practice it is usually more accura but little more office labor, to read vertical angles to a defini plumb-bob string (say, the top of the plumb-bob) just as they c to attempt to set the sighting point at the same distance below instrument is below its point. The $H.I$ and $H.S$ are read with a pocket steel tape graduated to feet and hundredths. In me of a transit it is customary to tape obliquely from the bottom o center of the end of the horizontal axis; this does not introd unless the distance is short. The following table gives the corre tracted from the oblique distance as measured on a transit of w the axis is 0.25 ft from the center of the telescope:

Corrections to Subtract from Oblique Measurements

Oblique distance	Correction	Oblique distance	Correction	Oblique distanc
0.6	0.091	1.1	0.026	1.6
0.7	0.066	1.2	0.022	1.7
0.8	0.050	1.3	0.019	1.8
0.9	0.039	1.4	0.016	1.9
1.0	0.032	1.5	0.014	2.0

rtical angles by transit. Since vertical angles can not e manner as horizontal, they must be duplicated and al angle of a traverse of any importance should be read the telescope normal and once with it inverted, and der to eliminate zero error of the vertical vernier. For isable to read both verniers, in both positions, and take the average of the four readings; this further compensates any eccentricity error in the vertical circle. While traversing by repetition angles, or by double deflections, no time is lost by reading vertical angles with the telescope in both positions; on an azimuth traverse, the only check is to read the vertical angle on the backsight as well as on the foresight, making two complete sets of readings of the taped distance, the *H I*, and the *H S*. The auxiliary telescope, when attached to the horizontal axis, gives vertical angles direct; when on top of the main telescope, a correction must be applied (Art 4).

Underground leveling is performed in a manner the reverse of that employed on the surface. The zero end of the rod is pressed upward against the bottoms of the spads, or other desired points; backsight readings are thus negative in sign, and foresight readings Sec 17, Art 18.) Elevation of a point on the floor is od right end up and recording the reading as negative

STANFORD LIBRARIES

e in this shaft, and their connecting line used as a base for
ey. Extreme care is therefore necessary in every detail of

experiment (5) that wires are liable to deflection if an air
er than 100 ft per minute is present in the shaft. The
is proportional to the velocity of the air current, but
s up or down the shaft is immaterial. A wire hung in the
shaft is more strongly deflected towards the long side of
wo wires be hung in opposite corners, their deflections
ctions and the bearing of the line connecting them at the
displaced. This is a more serious source of error than
he wires. It is therefore recommended that in a shaft
nt of air the wires should be hung at about the middle
ather than in the corners. If possible, the ventilating
ced or stopped while shaft plumbing is going on. If this
ortant work, board flues can be built from the top to near
ft, and the wires lowered inside of them; these will afford
lling water. A light bob should be used for lowering the
obs attached below. Freedom of a wire from obstructions

the wire, due to its diminishing weight as it comes out of ed, because the measurements are made on the wire at the n it were hanging vertically.

9. Notes and Computations

of notes, and every engineer is entitled to his own prefer- tem is equally clear to him and to the engineering staff. le to use a printed form, with headings printed or written mns than necessary. The transit man can then tell at a tem of information pertaining to each set-up is recorded, e next station. If a certain measurement is not required heck-mark should be made in the appropriate space, to t overlooked. The following headings are suggested for traverses.

Azimuth Traverse

	Tape	Vert angle	H I	H S	Remarks

Deflection Traverse

ouble def	Tape	Vert angle	H I	H S	Remarks

Angle Traverse

econd read	Tape	Vert angle	H I	H S	Remarks

lection traverse the narrow column under "Deflection" ials *R* and *L*. After dividing the doubled deflection (or alue may be entered in the first column, on the line below. f any measurement are taken, they may be entered one same column; it does not pay to economize note-book entered one after another in regular order, following the that station. They are preferably lettered, to distinguish ed traverse stations. In the case of an angle traverse by devote a whole or a half page to each set-up. The record be entered thus:

Angle 7–8–9

	First reading			Fourth reading			Final value		
	°	′	″	°	′	″	°	′	″
...	—	—	—	—	—	—	—	—	—
...	—	—	—	—	—	—	—	—	—
	Average.....			.....			—	—	—

The data relating to courses 8-9 and 8-7 would then be ent page in their appropriate columns. Sketches and remarks right-hand pages, which should have coordinate ruling.

Loose-leaf systems. Among the advantages are: (a) Page since a particular page need not spend more than one day und is possible to file together all the notes relating to a given section though they may have been taken by different engineers a (c) A complete record of all notes is constantly on file in the working at a distance from the office, the notes can be sent putation and mapping.

The forms should be printed on bond paper cards, say 5 by fit the clasps of a leather or aluminum cover, which should fully to protect the edges of the sheets. Duplicate copies are able, in order that the engineer may have a complete set as One way to make these is to have white envelopes ruled and like the cards, into which the cards fit snugly. One card and paper are put into each envelope, and a number of envelopes cover for the day's work. The engineer then retains the emp returns the carbon copies to the office.

Computations. The first step is to convert azimuths, defl into bearings, as described in Sec 17, Art 11. Next, red tances to their horizontal and vertical components, multiplying sine respectively of their vertical angles. Gurden's traverse help in this operation. Next compute latitude differences and courses, or take them from traverse tables. If a closure ca pute and distribute the error in proportion to the length of From the balanced latitudes and departures compute the c stations. If no closure can be made the coordinates are ca unbalanced latitudes and departures. Lastly, compute elevatio from the vertical distances, the H I and the H S, as describe following form will be found convenient for assembling the d putations.

Course	Azimuth	Bearing	Inclined distance	Vertical angle	Horizontal distance	Latitudes		Departures		Corrected latitudes		Corrected departures		Coordinates		Vertical distance	Height of Instrument

1. Mine Geologic Maps.....
2. Mine Models.....
Bibliography at end of each article

1. Mine Geologic Maps

Geologic study and mapping are especially useful in comple of this nature, in conjunction with mine development and e chiefly by large mining companies, though similar study is p at small mines. The surface and underground notes and sk office maps, omitting less important notations from field boo overcrowding. Where structure is complicated, geologic pla by vertical sections or by models.

Underground observations are best made in new broken rock and ore. In wet ground, the surfaces soo black slime, derived from moisture, dust, and products o ceals mineralogic characteristics and adds to the difficu deductions. In moving or faulty ground, also, inspecti be made immediately after blasting and before timberin tion is frequently found in wet or heavy ground. Pron always desirable, to enable those in charge to direct wo the waste of misdirected exploration. Observations sho level workings, but should cover stopes and all other o faults, sill-floor workings in wide veins become heavy, closely lagged. Plans and cross-sections must then be m (Fig 4). Frequently, when engineer or geologist is calle ogy, much of the ground is stoped and no information obtainable.

Each ore-deposit presents its peculiar problems; in taking keep in mind the purpose of his work, and the point of view of plicated vein and fault systems structural features demand s cases, mineralogic associations are paramount. It is importa from non-essential geologic data.

es that can be represented. The pitch or general trend of shoots or irregular shapes is well shown. A cross-fault, orizontal displacement on plan, often causes considerable in plane of vein (Fig 8). Longitudinal sections bring out junctions or intersections of cross-veins, faults, or changes

geologic maps: (*a*) to assist in reducing mining costs; mine; (*c*) to preserve a geologic record of mine for future erstanding of the mine geology by the superintendent, *in* is of prime importance for avoiding useless underground geology is complicated, it is rarely possible for the mine ntricate structural relations of veins and faults, however with the mine workings. Best results are obtained by n and vertical-section geologic maps, possibly aided by

glass-section models. Veins and faults are projected
probable positions indicated by dotted lines.

Such advance interpretation of geologic structure assists su
in planning the larger development of mine, and in searchin
segments of known veins. Level workings intended as perma
air or haulage ways, shafts, pump stations, and raise connec
laid out to avoid faults and heavy ground. Maintenance c
directly affected by nature of ground encountered; hence the
maps, showing probable areas of heavy ground. To have t
the geologist must follow closely the advance of mine openin
cut off by a fault or dike, no money is wasted in search for the
man and geologist must therefore work in harmony, so tha
faulted vein, the first round of holes may be properly dire
wide, or composed of more than one fissure, its entire width s
search for faulted segment is begun. Owing to irregularitie
quent tendency of vein fissures to branch, or change dip or str
structural details often assists in keeping an exploratory drift
fissure; and the proper subsequent procedure for exploring
gests itself. If the deposit be in sedimentary rock, mapping
or genetic relations, if any, between ore and certain rock strat
rences to minor fissures, bedding, or cleavage planes may also
of recorded observations.

Comprehensive knowledge of the geology of a mine
its length of life. The period of profitable operation
covery of faulted segments of veins; or new orebodies
study of the mine geology and of the workings of conti
logic investigation often reveals the nature of factors
tion. When a mine shows signs of failure, through faul
with depth, those in charge must decide on future cou
tions call for a shut-down, or a further expenditure base
sound judgment.

Geologic maps are valuable in case of apex controver
greatest moment to have reliable, detailed records of g
mineralogic character of exhausted orebodies and par
become inaccessible through caving. Such maps and
by models, may constitute the chief court exhibits in m
mine is to be abandoned and allowed to fill with water,
to date at time of closing, are of scientific value for subs
district, as well as of vital importance for future engine
properties. Lastly, each mine geologic record is useful
of the science of ore-deposits.

Introduction. A full discussion of this subject would be len relations between the objects of the business and the field of te practice. The aim here is to exhibit methods of mine organiz chiefly by means of concrete examples. The examples given are lated. Thus, the daily reports given under Cost-Keeping (Art 4 the discussion of Mine Records (Art 5), and both subjects are su fied by the extensive series of cost tables in Sec 21.

MINE ORGANIZATION

1. Business Management

Essentials of efficient operation are: correct unde ducing possibilities of the mining property; good techni ating skill; adoption of correct methods of finance. which the working organism rests is the stockholders, w the conduct of the business. In the case of the large corp actual control is usually exercised through leadership holders. Such a situation sometimes results in abuse because the body of stockholders feel that their votes ha the conduct of the business. Controlling groups some holders by paying unearned dividends. Conduct of th owner or by a small group of partners is usually mor necessarily so. In large corporations the management cally self-perpetuating committee of stockholders, calle tors" (see below). This board usually has power to buy

STANFORD LIBRARIES

s, to dispose of its funds, and to borrow money; it can
business, it is the mainspring of efficiency of the enter-
cess or failure.

may be divided into two groups: (*a*) those which
to working a given property, and when that is exhausted
ss; (*b*) those which contemplate perpetuating the busi-
end on a single mine, but by constantly setting aside part
om time to time obtaining new capital, or both, provide
opment of new mines. The second type of corporation
policy, and the Board of Directors is usually composed
branch of the mining business, to whom organization of
matter of vital personal concern (2).

Refining Co is an example of the second type of corporation.
ion of a group of three companies engaged in mining, smelting,
r, lead, zinc, gold, silver, and other metals. Combined capital,
presented by fixed investments and working capital in different
thousands of stockholders and probably 100 000 employes.
mate $10 000 000, and large sums are set aside annually to buy
old ones. Its general business has steadily grown, because it
d intelligently managed. Its Board of Directors comprises 27
ht be described as investors or capitalists primarily, though of
active administrators of the business. The remaining 18 direc-
ployes, who have been and still are experts in transportation,
nd executive work. The Executive Committee consists of 17
rs; the Finance Committee of 4 members of the executive com-
eral officers; President, 4 Vice-presidents, Treasurer, Secretary,
itor, Auditor, General Counsel and Assistant, and an Assistant
these officers are directors. The Vice-presidents are executive
artments. There are also 11 minor department heads and con-
m 4 are directors. The minor departments comprise sales of
y, heads of several important groups of mines and smelters,
gers. The entire group of about 40 business heads, financiers,
re the responsible organizers of the business. Subordinate to
mines or smelters.

Missouri, a much smaller corporation, is another example of the
out 1 100 stockholders (bond and note holders, number un-
eneral officers, 2 consulting engineers, 3 000 employes; total,
te investment: mining, milling, and power plants and acces-
ng plant, $2 000 000; transportation plant, $7 000 000; total,

2. Technical Management

f this part of mine organization are illustrated by the
h Lead Co (Art 1). Under the President of that com-
Managers; one for mines and mills (3 complete plants),
way, and 1 for the general service unit. In general, the
nagers, and the scope of their duties, vary in different
neral manager is put in control. Sometimes, as in the
of Lake Superior, this officer is called an agent. But,
ctive man, it is seldom necessary to interpose a separate
elf and the heads of naturally independent departments.
that one man shall be in direct control of a department,
d manager, general manager, superintendent, or general
aterial. Each such head has charge of all expenditures
accounts for them to the treasurer, but he does not
ount for the receipts from his department. These are
e general office, under direction of the president. The

department manager makes requisitions on the gene
to meet his expenses; hence his department really pr
he has no control, and for which he does not accoun
only the work done under him, and is called cost-kee

Organization data. Details of an elaborate organizatio
actual figures are for operations on a somewhat curtaile
force, there are 80 000 to 85 000 man-shifts per month, th
ployed each day would be only 10 to 12% greater than sho
curtailment results partly from reduction of employes, and
of working days. Normal production, 7 000 tons crude o
plants, Rivermines, Leadwood, and Bonne Terre, employ
office force of 51 men includes superintendents, master mec
ing agent, cost-keepers, time-keepers, stenographers, etc.
offices employ 10 surveyors and draftsmen, whose principal

is practically constant, and may be counted upon calculations. With a labor tabulation showing 400 m the manager of this mine can instantly calculate hi $2 300. Then, if he can calculate that the ore will day, he at once figures his daily income at about $ This illustrates the principle underlying the daily rec

Calculation of daily yield, however, is only mine, the records may appear somewhat as follows:

Working place	Tons	Grab sample assay, ounces per ton
A	26	1.06
B	19	1.96
C	110	0.32
	165	0.61

From this, the ore apparently is worth about $12 per ton. grab samples, as a rule, run high, and that it is safe to figu in this case, $9 per ton. Furthermore, if the 110 tons only 0.32 oz ($6.40 per ton, of which 75% = $4.80), and ton, stope *C* is plainly losing money, and it should immedi

Daily Statements. Some simple process of calculatio mine, and for each important working place in it. Referrin that the men employed in each subdivision might be ent Such a statement can be made on a horizontal line of a for day in the month. By filling it in daily, the number of m detail; also the daily product from the working places for month. Information of this kind is needed also by supe their several departments. Though the interpretation of telligently only upon the complete periodical cost stateme manager, superintendents, and foremen are intimately conn given in Art 4). The formal monthly statements are regu men, who receive them with only a mild interest and use sions drawn from the daily reports.

Mine maps. Sec 19 gives details of mine maps geologist's standpoint. Geology of a mine is an in formation conveyed by maps; but maps also ex namely: location of workings; depths, dimensions, tion of boundaries and approach to areas of disput more effective handling of ore, timber, waste rock, maps is an important aid in attaining efficiency o maps, from which dated blue-prints are made at inte furnishes the history of the development of a mine a casting its future. Lacking a comprehensive syste tion may be lost. In working a mine, details ac difficult to correlate unless they are recorded at once scheme. In general, the maps should be made in fol

vary according to the mine (14, 21, 23). In any case the fina
be brief and deal with totals carried forward from detailed dai
accounts can not be directly distributed to working faces ea
on the mine cost-sheet it is desirable to deal only with gene
ferring to Table 2, under the head of cost-keeping, the ac
follows: For DEVELOPMENT direct: miners, muckers, trammer
For STOPING direct: miners, shovelers in stopes, trammers
expense for filling. For GENERAL ACCOUNTS: hoisting, pumpi
explosives, sampling and assaying, surveying, watchmen, mine
dent, foremen, shift bosses, blacksmithing, repairs and rene
repairs and renewals to machinery, mine and shaft repairs,
pense, new construction, new machinery, tools, miscellaneo
heating. To these accounts the charges are made in the v
cost-sheet. The total of the mine accounts is apportioned
counts, development and stoping; in some cases a third acc
or exploration, is added. It is not necessary to keep a set
system. Best method is a system of daily reports, distrib
loose-leaf record sheets (23). To facilitate filing, all reports
loose-leaf form.

Besides the mine accounts, the following division of costs n
WORKING FACE RECORDS (Table 4), after cost-sheet totals have
to development and stoping. For EXPLORATION: trenching
diamond drilling, churn drilling. For DEVELOPMENT: shafts,

5. Mine Records

Working-face records (Table 4) are compiled fr
(Table 3), which gives for each working face and
miners, muckers, shovelers, trammers, timbermen, a
piston drill-shifts, hammer drill-shifts; also dyna
(fuse may be averaged per cap used), amount and
and tonnage of ore and waste hoisted. In addition t
reported on shift-boss report, any other supplies s
chargeable directly to a particular working face ma
Assays of ore and face samples are also entered, as
The columns of estimated cost are worked up when
general account averages (11, 12, 23).

The above data give: direct charge for labor (wh
taken from payroll distribution); direct charge for su
assay records, and advance made. Hoisting is appo
ported, and total machine drill cost on basis of machine
charges that may be distributed directly. The rema
cost-sheet may be made in proportion to the totals

Labor records. When a man is hired he shoul
slip, stating character of his work. This slip furnish
authority for putting the name on the payroll. A
should be kept, giving name, signature, local addr
for each employe.

Table 5 is a shift-bosses' loose-leaf TIME AND DIS
work satisfactorily at a property where it had been
duction, to get the shift-bosses' daily reports of wo
time book. By first making the distribution in tim

6. Major and Minor Operating Units

This distinction is exemplified in the organization of the St Joseph The major units of this property are: 3 complete mining and millin smelter, and 1 general service organization. (The last is the Bonne Cattle Co, which controls the surface of mineral lands, houses for em supply, etc.) These 6 units are not necessarily dependent upon on road could haul ores for other mines, and any mining plant could shi smelter.

Major units can be divided into smaller, or MINOR UNITS, independent. Thus, the mining plants consist of the mines, power plants. Carrying subdivision still further, the mines c of shafts (with their connecting workings), which may be qui one another, but are dependent upon the power plant and a and each may have a choice of several mills for treatment of

Economy demands that each major unit be run at full capacity. more ore than is sent to it, part of its equipment and first cost is versely, if more shafts are operating than are required to supply th viously being worked at reduced capacity, and one or more of them s In the case of the St Joseph Lead Co, though 13 shafts out of 24 h within the past few years, the total output has been greatly incr wholly dependent on one another are illustrated by the items of Hoisting engine, pumps, haulage plant, shaft timbering, etc. must b in repair, whether the output is large or small. Therefore none of th be developed out of proportion to the others.

Efficiency engineering consists in a study of units, in ord mum output from each. To this end it is necessary to asc are effective and which are only relative.

STANFORD LIBRARIES

machine drill is to mine ore cheaply; the units comprised
st of the machine and repair parts, compressed air, explo-
, for breaking say 30 tons, is about $8, comprising: wages,
ir, $1.50; explosives, $3. Economy lies in getting a large
t be uneconomical to emphasize any of the minor units
ence of the others. Thus, by reducing wages, inefficient
lts; excessive economy in repair parts might cause costly
of compressed air would result in feeble drilling; reducing
ecessitate an excessive footage of drilling. It would be
the cost of operating a drill from $8 to $7 per shift at the
age broken from 30 to 20. Conversely, it would be good
hift if the output could be increased in greater proportion.
chine drilling is the cost per ton of breaking ore, and not
line of reasoning leads to effective management and cost-

Bibliography

Introduction

been prepared by Heath Steele, along the lines adopted in
Finlay, published 1909. They present typical examples
s, showing actual costs as well as illustrating systems of
acticable to discuss costs of mining intelligently unless their
tood. Three distinct conceptions have been adopted: (*a*)
including dividends, sums loaned out, nor mere book en-
l money spent on property, on construction of plant and
actions; (*b*) Amount spent in operating mines and mills,
n plant, financial transactions, etc. These costs take the
d for a long period. This average sum (termed "depreciа-
rating expenditure, to give total cost. This cost will never,
h expenditure for any one year, but should approximate
umber of years; (*c*) Amount spent on operation, omitting
will not agree with actual expenditure, invariably falling

pruce poles cost 1¢ per in of diam per linear ft of pole. Pine diam per linear ft. Avg cost per running ft of both, 5.33¢.

he gravity tram is used in lowering ore from stopes down track requires.

ir distribution for sharpening drills shown in Table 22.

ir-drill repair parts are made in the company's own shop.

his work consists of miscellaneous jobs around the shaft; taking e, and other small jobs.

This account is for handling ore from the 3 400- and 3 700-ft levels s at the 4 000-ft station.

Fuel oil for reheating, to the amount of $120 and included in e 23, should be charged direct to hoisting.

No 1 is an 8-stage pump lifting 240 000 gal per 24 hr, 1 400 ft ing 140 000 gal per 24 hr, 475 ft. The 8-stage pump has been age pump, effecting a saving of $400 per month in power. No 2 g 220 000 gal per 24 hr, total head 725 ft, avg head about 350 ft. nd 17. The average loss per ton of ore treated is: for shoes, ; for dies, 0.525 lb cast iron; liners, 0.094 lb cast iron; cam-iron, per ton of ore.

and 17. Of the rock sent to the mill the rock breakers at the % as waste.

and 19. Mill foreman looks after concentrators, and cyanide nills.

These figures were obtained by air-meter tests on the various akage was obtained by the number of revolutions required on the e air pressure at 100 lb. The leakage had been reduced from er month, or over 25% of compressor capacity.

ren in Table 26 cover operations during periods when the 100-mill in operation. The company operated a 20-stamp mill up efly, the operations in this mill consisted of: crushing by 8- by eying by 14-in by 165-ft belt, running on a 20° incline to stamp stamps, 109 6½-in drops per min, through 12-mesh screen; ing, reamalgamating; separating to sands and slimes; con- s and agitating slimes; filtering through Butters' filters; zinc and precipitates to bullion and concentrates to smelter. The was practically all oxidized. Table 27 gives an example of the ained at the plant, excluding depreciation of plant.

ble 27. Operations, 20-Stamp Mill

Average value per ton, $37.15. Net recovery, 93.80%, as ion, 41.40%; concentration, 18.20%; cyaniding, 34.20%.

Example 5. Portland Gold Mining Co (

In 1910 the Portland commenced treating its waste dumps; tons were treated, yielding $113 253. In 1911, 120 961 tons, $3.51 per ton, were treated. The yield from this ore was $345 5 81.4% and profits $128 738, indicating a cost of $1.80 per ton fo Regular ore mined amounted to 50 259 tons, averaging about total cost of mining and realization was apparently about $1 mine ore.

amond drilling data for 161 holes in this district, totaling 77 135 ft, 57.93¢ per ft of hole, as follows: operating labor, 31.28¢; power, 4 per kt, 12.2¢; operating materials, 2.82¢; labor (maintenance and (maintenance and repairs), 3.14¢; depreciation, 0.63¢. For single om 50¢ to $1.50 per ft. The rate of drilling is about 25 ft per e of about 50 to 55 ft of holes are drilled per ton of coal used at

es and mills costs approximately 1.16¢ to 1.43¢ per kw-hr. Pur- osts about 1.62¢ per kw-hr. Steam power costs about 1.21¢ per range from 7¢ to 12¢ per ton and underground haulage from 6¢

Shift bosses, $3.10 per shift; drillers, $2.40; backhand drillers, Loaders, drivers, cagers, car hookers, trackmen, stablemen, ncline hoistmen, and pipe fitters, $2.40 per shift. Underground ressor engineers, shaft carpenters, and electricians, $2.10, $2.25 erground blacksmiths, $2.55; helpers, $2.15; surface blacksmiths, underground diamond drillers, $2.60. Hoisting engineers and . Machine shop mechanists and blacksmiths, from $2.10 to m $2.20 to $2.60. Mill shift-bosses, $3.10; mill workers, from

5.5 tons of ore are secured per day per man employed in the 20 to 25 tons are milled per day per man employed in the mills. at mines and mills, including operating heads, the average is a nan per day.

STANFORD LIBRARIES

Example 17. Zinc Mining, Jopl

(Furnished by J. L. Bruce, Mgr, Butte and Supe

The ore deposit of the mine whose costs are covered by "sheet ground." It occurs in a nearly flat vein or blanket, 100 and at a depth of 200 to 225 ft below the surface. Th and covers an area of 100 acres, most of which is compe gradually becoming poorer in valuable minerals in lateral ex grade ore unprofitable to mine and mill.

The valuable minerals are sphalerite and galena, which o interior of lenticular openings or completely filling former more generally as crystals enclosed in secondary flint whic primary chert formation. The gangue consists of one particu chert formation, together with the secondary flint, there bei no other rock material. There is present a small amount o the form of marcasite. That particular stratum of chert occurs is overlaid by 6 or 8 ft of chert of similar character, extending to the surface. Below the ore stratum are about which lie alternating strata of limestone and chert. The str orebody is capable of supporting itself over spans of 30 ft, a 100 ft. The limestone above this chert is even stronger, so approximately 10% of the area is allowed to remain (witho its valuable contents) as pillars from 15 to 20 ft in diameter.

In mining the upper 7 or 8 ft of the orebody the work rock drills, holes from 6 to 8 ft deep. After chambering ou with a small charge of dynamite, they are blasted with 7 to the hole. A round usually consists of 5 holes drilled parallel to which they are to break. Three holes in front are fired holes. After the face between two pillars has been advanc to 16 ft back from the face is made, a 3½-in drill on tripod hole under the bench to about 16 ft in depth. This hole is c 2 to 3 sticks of dynamite the first time and 15 to 30 the seco hole is large enough, from 75 to 125 lb of 40% gelatine powd hole may blast as much as 600 to 700 tons of ore, often loos of 25 to 30 ft. The broken ore is loaded into cars of 2 700-l mules to a central gathering track; whence it is taken to th locomotive and hoisted in automatic dumping cages, which grizzley (with bars set 6 in apart) above the mill bins. Pieces of grizzley are broken with a sledge and passed through if they sufficient quantity, otherwise this oversize is sent to waste d

Practically no development work was ever done on this carried on by churn drilling, the average cost of which was a cost of plant, exclusive of shaft sinking, was $60 000 or abo pacity. This includes cost of mill, power plant, compressor smith shop, etc.

The mill has a capacity of about 600 tons and the ore is into a 10 by 18-in Blake crusher, then to 30 by 16-in rolls, ji description of milling process employed at this property may *and Mining Journal*, 1912, Vol 93, pages 405, 459, 501, and

Power. Steam power is used for hoisting and compres mill-drive and pumping. Steam power has been generated gas, which costs 12.5¢ per 1 000 cu ft, fuel oil at a cost of 1.5¢ $2.25 a ton, delivered at the plant. The cost of steam pow plies, is about 0.8¢ per hp-hr; cost of electric power, about compressing air for rock drills averages about 19 h p for ea shift. Mill and mill pump consume about 165 h p and mine

Labor. On average production of 500 tons per day, mi and milled in 2 shifts, the distribution of labor is approximat

Description of Working Conditions. The major
from steam-shovel pits. The capping, averaging sligh
moved by steam shovels, working on benches averagin
done by churn drills, one drill serving each shovel. D
20 ft from top edge of bank, and carried to a depth of 5
hole is first sprung with dynamite and then charged wi
pending upon the ground. The heights of benches vary
grades to the various overburden dumps. Eight 1
saddle-back locomotives, and 50 18-yd one-way dump
There are two shifts, 9 hr each.

The ore is of the disseminated porphyry type, and
monzonite porphyry intrusive. Analysis of ore:

Au	Ag	Cu	SiO_2	Fe	C
0.015	0.04	1.6	71.0	4.0	

The ratio of concentration as determined in practice
concentrates. Ore is hauled from mines to concentrato
level elevation at mines, 7 250 ft; at concentrator and
crushing is done by gyratories and rolls, and fine crush
Chilian and Huntington mills in others. Concentratio
Concentrates roasted in 16 18-ft McDougall furnaces.
in 5 reverberatory furnaces, with California fuel oil.
Pierce-Smith basic converters. The power house has t
ators. There are also 3 blowing engines of 6 000, 1
respectively, compressing air to 15 lb for the converting
consists in removing the waste overburden from the o
an average of 2 752 000 cu yd of overburden is remov
being 2 850 000 cu yd.

Example 26. St Lawrence Pyrites (

(Data furnished by F. T. Rubidge, V

Description of Working Conditions. Ore occurs in thickness, and inclined from 30° to 45° from the hori and laminations of gneiss of varying thickness occur i gangue which makes drilling easy, but about 50% of c reality a pyritic gneiss.

Only one mine is worked. Hoisting shaft is single co is unbalanced. Two veins are mined, about 75 ft of ro done by hand, two men to a car. Cars are loaded m though some shoveling is necessary. Average load, 60% of ore is dumped directly into skip; remainder int age hoisting depth, 250 ft vertical. Stoping method go overhand and part underhand. No timbering except f 55-ft centers, are left, making stopes 40 ft long. Hang defined, and hanging stands well.

Table 113. Average Mining Cost per Ton I

Underground		
Development in rock	$0.004	Shipping f
Development in ore	0.183	Breaking
Stoping	0.279	at mine
Timbering	0.015	Engineerin
Tramming by hand	0.146	Administr
Hoisting	0.026	ing supt
Skip tenders	0.010	Warehouse
Pumping	0.033	General su
Underground tracks	0.006	Insurance
Supt, bosses, and timekeepers	0.021	Taxes
General underground expense	0.031	
Total underground mine exp.	$0.754	Total surf
Total mine operating expense per 2 240 lb,		

Note.—These 1912 figures do not include depreciati of home office expense, but do include all maintenance

The charges for development are actual charges for in excess of that required for amount of ore extracted. ft of drilling was necessary, while 2 369 ft was actually c to development, although most of it was incidental to linear ft being 1 575 for the year.

During the year the drilling equipment for stoping w to hammer drills, the latter including air feed and "Ja for January shows 22.3 hammer-drill shifts and 314.8 pi record of 13.6 tons broken per drillman shift (includin cember record shows 257.9 hammer-drill shifts (of wh shifts) and 3.6 piston-drill shifts, with a combined reco (helpers used only on the piston drills).

Of total cost of 88¢ per ton, the total labor on surfa 50¢, excluding administration and mine office expense 19.9¢, and power 11.7¢ per ton. Power is purchased 0.75¢ per kw-hr; hence 14.6 kw-hr were required per drill equipment and the substitution of electrically-dri the power has been reduced to about 8 kw-hr per ton, of 14.5% for hoisting, 9.5% for pumping, 8% for crushi underground hoist.

6. St Lawrence Pyrites Co (*Concluded*)

ures are given for 1912, because the mine has not worked
13. Better results are now obtained than during Dec,
igures taken from stope records show:

WAGES

1. "Day's Pay" or "Comp

Day's pay system, an agreed amount of wages work, is open to the objection that it entails an u to avoid waste of time and supplies. But, for ma engineers, mechanics, foremen, office force, and mi pay system is the only practicable one.

For underground work, day's wages are also preferable in those mines in which the minerals are irregularly dist in the separate handling of ore and waste, or in which th demanding slow and painstaking operation; both of thes by any system which aims to promote speed.

Day's wages compared. Data in Tables 1 and of comparison for estimates of mining cost, since la ponderating factor (power and supplies being the tion. Wages for the same class of labor are natura where supply of workmen is limited, living conditi is expensive.

2. Sliding Scales for

Sliding scale arrangements aim to establish price of mine product, where latter is subject to vantage of workmen and operator.

Most noteworthy examples in U S have been: PE First award of the Anthracite Strike Commission (1) increase of 10% in mine wages over those in force duri vision as a minimum basis, award No 8, effective Apr crease of 5¢ above a base price of $4.50 per ton domesti harbor points), wages should be advanced 1%. Aver p by an accountant appointed by a U S judge of the 3d contributed by the mining companies in proportion to tinued in force by renewals of the original agreement, but was abolished by mutual consent May 20, 1912. mine managers and organized laborers, June 1, 1912, m workers was set at $4 per day, while copper sold for 17¢ it sold for 15 to 17¢; minimum for surface labor, $3.25

3. Contract, or "Piece-rat

Advantages of contract system rest on the men work more diligently, skillfully, and efficien employer. The system in some form has been ap mine operation. From standpoint of an operat promote speed, reduce unit costs, and diminish e contractor generally obtains better returns and than a day laborer; adoption of contract system most invariably proved mutually beneficial. Ope with certainty on ultimate cost of a given undert to reap reward of his energy, skill, and resourcefu

Drawbacks of contract system, in general, workmen whose interests do not exactly coincid difficulty arises in the enforcement of standards safety. (*b*) Discontent is sometimes engendered a contract, or by refusal of manager to renew a co are unduly lucrative to contractor. Disputes ov work performed are also frequent. (*c*) In metal-m large production is likely to reduce grade of outp checked by levying a fixed charge for hoisting or

Applicability of contract system. For above most successfully applied to operations connected mineral deposits, notably boring, shaft sinking, tu winzes, and raises, and, in general, wherever size of rock fairly uniform or ascertainable, or the c readily measured and inspected.

Examples. COAL is almost universally mined on co on tons or bushels delivered at tipple (Art 11); narro mines is contracted at so much per linear yard, to speci for the coal obtained; "brushing" (taking up bottom s afford necessary head room) is contracted at so much for an agreed width. METAL-MINE STOPING has not factory contract basis, except on the Rand, where rich zone are comparatively uniform over large areas; also at mines, and at other mines characterized by well defined richness. SHOVELING AND TRAMMING are operations w

s because it is often impossible to arrange this work so as to avoid example at Joplin, where 15¢ per ton is paid for shoveling into cars distance of 150 ft. Interesting example of HOLE-DRILLING COS- land, B C (2) for both development and stoping. Machine drills asting crew 1 shift. Cost per ton stoped reduced from $0.865 to , from $11.14 to $8.79. Rate of drifting increased from 50.8 to t sinking, from 27.2 to 58 ft per mo; aver earnings increased by n was later abandoned there, and at other mines where introduced, d extra work of measurement thrown on shift-bosses.

similar work, vary as widely as actual costs; hence not instructive e. For costs, see sections relating to the several operations; in uld be allowed a profit of at least 20% above actual cost, this being ing to company by reason of greater speed. Contractor should furnish his own blasting and other supplies; arrangements as to f machines, tramming facilities, sharpening of drills, bits, repairs, vidual preference.

4. Bonus, or Premium, System

system. From operator's standpoint, two chief draw- ontract system are: difficulty in maintaining standards of that contractor reaps practically the whole benefit of re- ion. Bonus system consists in setting a minimum daily or inimum wages rate based on aver performance); work per- ned) in excess of the minimum is then paid for at an addi- ated that the employer shares the saving in operating cost, n more rapid work. For elaborate comparison of several ibliog (3).

(a) At Franklin mine, IDAHO SPRINGS, COLO (4), 4 by 7-ft drift, tramming, was advancing 3.6 ft per shift, at cost of $11.97 per ft ; helper, $2.75; trammer, $2.50). On establishing bonus system, ance of 90 ft per mo, progress rose to 6.8 ft per shift, at total cost er ft was bonus. Drill runners' wages also rose to $6.58 per shift. v (5), 5 by 7.5-ft drifts were run by two shifts of 2 men each. er, $4; shoveler, $3.75) were paid for aver advance of 1 ft per man nthly). For advance in excess of 4 ft per day, bonus of $1 per ft mbo and Laguna mines; 50¢ in Combination mine. Aver advance al cost of $6.20 per ft, of which $3.77 was for wages. (c) Stoping ne (6) was done by both hand and machine. Miner was charged 45s for gelignite; 2s 9d per shift for native helper. For machine fathom (36 sq ft × thickness of vein), minimum wages of 27s per Of earnings over minimum, one-half was paid to miner, and all e canceled. For hand work, rate was, 63.5s per fathom; guaran- shift; surplus divided as above. Machine drifting was contracted 80 ft per mo; bonus of 5s per ft per mo in excess. At a LAKE (*E & M Jour*, 96, 1177), 2 men, working 24 shifts per mo, at $3.25 were required to break 900 tons per mo (18.75 tons per shift at f 10¢ per ton for output above 900 tons. Supplies not charged to ded 7 or 8¢ per ton, in which case excess was deducted from bonus.

5. Cooperative Systems

s is sometimes arranged by permitting employes to buy ny, their employer; additional incentive to participate in offered in form of a discount from market price of shares, a onus, or an installment plan of purchase.

on, in 1903, instituted a plan by which common or preferred shares oyes upon easy terms, with benefits beyond those enjoyed by ordi- mber of shares which can be subscribed for depends upon the

olished by fountains, cascades, or flowing over dam, is useful also, when followed by filtration, for removing iron.

valuable help for curing turbidity and diminishing bacteria, orage or filtration. Coagulant commonly used is alum, 1 gr eam of water entering first storage reservoir. Coagulating uires presence of lime, which must be added if not originally .

ss (35) can be reduced by addition of slaked lime in quantity suffi- CO_3, which holds $CaCO_3$ and $MgCO_3$ in solution (say 1 lb per 1 000 lness). Water which is both turbid and hard, requiring an exces- an be more cheaply clarified and softened by lime.

hen properly conducted, will remove all turbidity, practically than one-half of color. Two general methods are: (*a*) slow pressure or mechanical filtration.

truction: a shallow reservoir, with water-tight sides and bottom, re advantageously of concrete, sloping towards one corner. Area to 40 000 sq ft; small bed requires more frequent cleaning, but can cted against freezing; advisable to build at least 2 beds, for alter- ing system of tiles with open joints is laid down, leading to dis- e next covered by 6-in layer of coarsely broken stone; 5 successive and screened stone or gravel, of diminishing coarseness, are then a layer 30 to 40 in deep of sand. Best sand for upper layer is of 3 to 0.4 mm diam, and of nearly uniform size. Water to be filtered voir to depth necessary to cause percolation at the desired rate of descending velocity; the slower the percolation, the more complete . When upper layer of sand becomes clogged, its surface is scraped of 1 or 2 in; when thickness of sand remaining is reduced to 12 or e added or the removed portions may be washed hydraulically and gging of sand filter increases in proportion to amount of turbidity h excess of algæ; in extreme cases, desirable to apply preliminary filtration, or coagulation.

rs are more commonly used after preliminary treatment just nitting water under pressure up to 10 to 12 lb per sq in, per- e rapid, up to 150 in descending veloc per hr, and, if properly efficient. Installation of mechanical filters should be super- n hydraulic engineering, and their operation must be con- eful control.

is most advantageously applied to water which has pre- d by sedimentation, coagulation, or filtration, for purpose of against pathogenic bacteria. Two substances most com- OCHLORITE of calcium ($CaCl_2$, containing about 30% Cl) and ; in either case, usual proportion is 0.3 to 1 part free chlorine The $CaCl_2$ must first be emulsified with water, and kept in utomatically into stream of water to be treated; liquefied ottles, costs 8 to 10¢ per lb, and requires specially designed mployed for disinfection in Europe; mechanical difficulties d its installation requires service of an expert; has not yet with chlorine in U S.

mp service, a useful device (38) is a water-tight canvas bag, 20 in aving loops at top for suspension and one or more nickled f-

at bottom. $CaCl_2$ is put up in sealed glass tubes holdi

bacteriological action requiring O; sterilized timber does not decay. ed by hot, humid air, and probably by the crushing of timber, as in loyed in the block-caving systems, in the Lake Superior iron mines, s, and elsewhere. Adjacent to crushed masses of timber the deple- ction of CO_2, accompanied by heating, is so marked as to cause dis- s.

men and animals in well-ventilated mines are of small importance rces of gaseous impurity, but are a large factor in metal and other cial ventilation, especially in headings or stopes unconnected near workings. An aver man under different conditions, from complete l work, consumes 0.25 to 4 liters of O per min and exhales, together O, 10 to 20% less CO_2 than the O consumed, or 0.2 to 3 liters. For ions in mines the aver exhalation per man is between 2 and 3 liters of inhales 30 to 60 liters of air per min. If the CO_2 content of adja- re is to be kept to 1% or less, then 7 to 10 cu ft of pure air per man , and about 3 times this amount for each draft animal (Art 5).

f lights, other than electric, has important effect in inner s where ventilation is slow, particularly in metal mines with

. Paul (Bureau of Mines tests): a sperm candle, burning 1 gm, con- per hr; a miner's brass lamp, burning 4 to 6 gm oil, consumes 0.8 r's lamp, burning 8 gm oil, 2.16 cu ft; a driver's lamp, burning 6 gm ft; ordinary type of miner's carbide lamp, using 12 to 14 gm carbide. These tests show that a lamp consuming 1 cu ft O per hr uses up all r; and, to keep the depletion of O within the safe limit of 1%, such a 1 ft air per hr. The amount of gaseous impurity given off by large places is so considerable that, where air currents are feeble, the use of s is advisable.

om strata. CH_4 (Art 2) is the most important and dreaded n collieries. It is probably derived from coal-forming mate- n due to heat and long-continued pressure. There is no between the amount of gas retained in the strata and the mation; the quantity seems to depend more on geologic struc- boniferous to Eocene the coal measures when opened are CH_4.

ons, especially the contorted Appalachian anthracite folds, produce lat practically undisturbed beds of the middle interior fields. Also, l beds of the Rocky and Cascade Mts, more gas is found than in the f central Wyoming. But this rule is not invariable, and seems to be depth of impervious cover, giving vertical pressure and less chance Sec 14, Art 2).

H_4 in the strata appears to bear a rough relation to the press equal to depth of bed below water level, but this is subject s according to permeability of strata. CH_4 is held

Effect of high temp and high humidity
Either condition alone is bearable, but when

results. At moderate temp, say under 70° F, relative humid-
s unobjectionable, and a nearly saturated atmos is not serious
in a good current of air; otherwise it is oppressive and a day's
inishes with a further rise in temp and saturation.

4): "At temp of 93° in still, saturated air I found that, though I was
ist and doing practically no work, my temp rose 5° in 2 hr, and was
when I found it necessary to come out." Church (monograph on
880) reports that "the immediate results of high temp and hot vapors
ness, dizziness, fainting, vomiting, and as graver results, insanity and
s in the Comstock mines at that time positively traceable to heat
hole. Probably heat increases the bad effects of powder fumes and
rd, referring to the same mines (1883), states that the ultimate effect
not easily noted. Power of recuperation appears to be extraordinary;
in is intense and frequent, there may be no lasting injury. Young
"Local physicians say that the average working life of Comstock
es 25 years, and that they show no greater susceptibility to disease
lents." Miners working stripped to the waist are careful not to expose
drafts; on passing from a hot to a cold place a heavy coat is used.
noved before going to surface, or trousers and coat are worn over them.
nd cold showers after coming off shift. Frequent drinking of, and
sts, arms, and head in ice water are resorted to. Frequent rests are
oling rooms, so situated as to receive the freshest and coolest air. In
, cold water from a hose is turned upon the miner while at work.
F, with 50 to 70% relative humidity, and air moving at 200 to 300 ft
prevent efficient work, nor is it particularly uncomfortable. Temp of
above conditions, considerably reduces efficiency. Same temp, with
moderate air velocity, greatly impairs efficiency; higher air velocity
nore bearable, but miners can not work long at one time. Temp of
turated atmos with no current is bad, and prolonged exposure to it,
, is dangerous. Temp of 90 to 98°, and saturated currents of 400 to
ery trying. Vitiated air impairs labor efficiency more than high temp.

urities without toxic effect, but causing oxygen deficiency, in-
EFFECT OF OXYGEN DEFICIENCY near sea-level or below it is the
n of O due to lower atmos press; as in mines at high altitudes.

⅙ less than at sea-level, as at Denver (5 000 ft), is not noticeable;
Leadville (10 000 ft), violent muscular exertion causes rapid breath-
rt action; continuous exertion causes faintness. The O present in a
eadville is the same as that in a sea-level mine, where the O has been
to 13.8%. At top of Pike's Peak (14 147 ft) the barometer registers
present corresponds with but 12% O in air at sea-level. People be-
owever, and live at these and higher altitudes. In Peru, Bolivia, and
ere are many inhabitants above 15 000 ft.
4) that a person not exerting himself will rarely notice anything un-
entage of O falls to 10%; breathing then becomes deeper and quicker,
he face somewhat dusky. At 7% there is usually distinct panting,
nd the face assumes a leaden blue color; the mind becomes confused,
ed, though the subject may be quite unaware of the fact. IN AIR CON-
of consciousness occurs within 40 sec or less, without warning symp-
dentally putting their heads up into a roof pocket of CH_4 have almost
nconscious. In a test made at the Pittsburg station of U S Bureau

The parts of the lamp are: *a*, iron hood; *b*, iron bo gauze; *d*, metal chimney; *e*, brass ring; *f*, glass globe; ring; *h*, 5 brass standards; *i*, wick adjuster; *j*, wick fount; *l*, key lock; *m*, circle of ventilating holes. B combustion chimney it gives much more light than lamps. Objection to the chimney is that it conceal flame if the latter gets too high on account of fireda remedied in recent English modifications by making combustion chimney of glass.

Marsaut lamp differs from the Clanny chief 2 or 3 concentric gauzes above the glass cylinder air spaces between them, which widen toward reducing the diam of the inner gauzes. It is muc the single-gauze unbonneted Clanny, due to ret the 2 gauzes of the escape of the burned gases, a blanket of non-explosive gas restricting an int sion. Fig 6 shows a BONNETED MARSAUT.

The parts of the lamp are: *a*, steel hood; *b*, steel bon iron gauze; *d*, inner iron gauze; *e*, upper brass bushi rings attached to gauze; *g*, asbestos washer; *h*, 5 bras *i*, glass globe; *j*, flat cotton wick; *k*, copper wick adjus brass ring; *n*, brass ring; *o*, brass ring; *p*, brass oil ring for washer; *s*, key lock; *t*, vertical openings fo Marsaut concluded that: (*a*) a small-diam lamp, like

me susceptible to explosion is small; (*b*) a lamp without a glass nal explosions, because the glass confines the gases and acts like a st to reduce diam and height of glass); (*c*) a conical mantle is safer f internal explosions than a cylindrical mantle of same capacity; f combustion plays a part in preventing in- is not advisable to guide them by a chimney eseler). Marsaut also found that an iron rass, a brass lamp giving only 70% of the iron lamp of same design. Brass has higher ot, and makes oil viscous. Brass is easier to nerally used, though some lamps have cast-

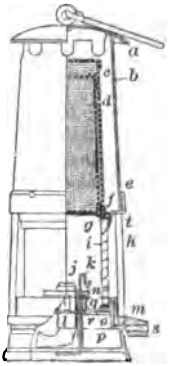

Fig 6. Bonneted Marsaut Lamp

ut lamps. The original Marsaut has a baffling air-feed which is very marked hence the glass may be smoked, giving But it is a good lamp for testing gas.

mination have been improved by various Marsauts are today the most favored safety Among them are the DEFLECTOR and PRO- are similar in principle, the air feed being es of combustion. In the earlier modifica- he gauze is shielded, and an angle diaphragm d extended to the gauze. There is a perfo- the glass. The entering air is deflected up- ring, and is thrown downward through the ss cylinder. Burned gases pass out through upper part of gauze. ications use the full bonnet with holes around the top, for escape of er 1 or 2 gauzes; 2 being considered safest. In some kinds a dia- used to separate upper and lower part of the gauze for outlet and ntering under the bonnet through slotted holes in the ring to which ed.

is an improvement on the Clanny. It has an inner glass chimney with an inlet under the glass, the air entering the lamp through the glass, passing down between the 2 glasses, and up inside the inner one to the flame. This design promotes good combustion. The gauze is also protected by a metal bonnet. Though it has good points, this lamp is not in general use.

Ashworth-Hepplewhite-Gray lamp introduced several new features (Fig 7). It is bonneted, with bottom feed, the air entering through 4 hollow standards. Air is drawn into these close to bottom through holes closed with slides, or at the top, so that tests may be made for a stratum of firedamp close to the roof. One of the standards may have an extension for testing for gas in a roof crevice or among timbers. Air passes from the standards into a circular groove within the brass fount, thence up through small holes to the flame (in this respect returning to one of the features of the Geordie).

The parts of the lamp are: *a*, aluminum hood; *b*, brass bonnet; *c*, brass gauze; *d*, copper ring on gauze; *e*, asbestos washer; *f*, brass-tube standards; *g*, glass globe; *h*, round cotton wick; *i*, wick adjuster; *j*, tin burner; *k*, insulated tube; *l*, asbestos washer; *m*, brass ring; *n*, oil fount; *o*, locking screw; *p*, brass gauze; *r*, lower air inlet; *s*, upper air inlet; *t*, adjusting ring for air admission. As usually made it has a flat wick to increase illumination. It is a good working lamp, though the large standards cast objectionable a frustum of a cone, which assists in throwing light upward. The and the bonnet has no opening except through the top, the burned ugh radial holes above a restricted opening. Thus the spent ga:

drawn from the individual figures. In 1914, ou
thracite district, 44 men were killed by gas explos
7.4%, or about the aver annual rate. As anth
and as the anthracite district is much more gaseo
tricts of the U S, the true proportion of gas fatali
country is probably less than 7%.

Firedamp accidents are mostly preventible by care
panies. The chief factors are: FREQUENT INSPECTION
men and GOOD VENTILATING METHODS (including large
room breakthroughs or crosscuts; use of line brattices,
in place of doors; use of double and triple doors; and
doned but open workings should be well ventilated,
securely walled off. Walled areas giving off firedamp
by drill-holes from surface. In gaseous mines, regular
valuable in controlling ventilation. In mines where
classified as gaseous or not) SAFETY LAMPS or PERMI
should be used (Art 9, 10). Mixed lights in the same
safety. PERMISSIBLE EXPLOSIVES (Sec 4, Art 9) should b
sives (black powder or dynamite). Machine-mining in

m explosives, other than those leading to gas or dust explo- 1911–14 4.9 to 6% of the total fatalities. They are chiefly premature blasts, due to accidental ignition of black powder utting fuse too short to allow time to get out of danger, forget- st fuse while lighting others, or getting tools out of the way; tamping bar. Only wooden bars should be permitted. Even rs are unsafe; (*c*) returning too soon to investigate apparent electric firing, a lead wire may come in contact with a coal- under power, or a power line, or with an unprotected dry cell y.

s safer than fuse, provided that, where electric coal cutters are em- the leads are kept in contact and covered with insulating tape until the machine and its leads. If electric firing is by battery, the latter ge) should be so constructed that the binding posts are not in circuit ring-opening button or lever has been pressed to close the circuit. AGNETO BLASTING MACHINES are preferable for safety. Use of power s to trolley lines is dangerous. For electric firiag from the surface, parate insulated circuits, and switch cutouts at mouth of every entry to prevent accidental stray currents entering the firing circuit (38). tically prevents accidents from misfires, if a delay of not less than 5

sfires may be necessary in coal mining, because if another hole y and shot, the first charge might be set off by concussion or g less burden blow out and ignite coal dust. It requires care, p is in outer end of charge. If another hole is drilled, every- outbye should be wet down before shooting.

gases from explosives in a well-ventilated colliery is rare, and nless coal or a pocket of firedamp is ignited, thus adding afterdamp or unless explosives are burned instead of detonated, by using too Art 10). REMEDY is to delay entering the working place until the t.

flying pieces of rock or coal from blasting are due to care- part of the victim in not getting to a place of safety, or the adjacent working without notification, or in not guarding the orking place after lighting a fuse, or while connecting up the ther point. Where workings have several entrances it is well iners with PAINTED WARNING BOARDS, to be placed across or trances not guarded by the shot-firer.

n mine gases caused 8 to 33 fatalities annually in 1911–14, or only he total. Except in case of explosions and fires, which are not in- tle excuse for such accidents. They are generally due to entering nnecessarily. To prevent careless miners from so doing, such places ventilated or permanently wall off.

m electricity (shock or burns) caused 76 to 89 fatalities -14, or 2.87 to 3.63% of the total. Some were from touching trolley or power lines, some from improper insulation and in- es and motors.

accidents might be prevented by safeguards, such as: trolley guard- wire is less than 6.5 ft above the roadway; guarding by boards or er cables or preferably by rubber covering and sometimes armoring; o prevent grounding of wires. In working places or traveling w

dust, beyond the influence of the agency that brou
hence the flame will die away and it is not consider

Propagation is the continued inflammation of ga
as far as the gas or dust zone extends. It is syn
necessarily violent.

Explosion, while practically synonymous with p
erable dynamic force, advancing as a moving zone o

Inflammation in gas mixtures is transmitted
of heat by radiation and convection, and by such
expanding gases that each layer in succession of unb
batically and raised to ignition temp. Thus, when t
is almost instantaneous, and with certain gases the
velocity in tubes of uniform size and character.
Berthelot (1881), who termed it "l'onde explosive"

Detonation-wave is the term given by Dixon
He states "the rate of the explosion-wave is a defini
mixture; the wave travels with the velocity of sou
moving rapidly *en masse* in the same direction."

Retonation-wave (Dixon), "l'onde retrograde"
pression traveling backward through the spent gase

Reflection-wave (Dixon), "l'onde reflechie" (L
reflected from a closed end or other contraction o
irregular galleries these waves are numerous, and
the spent gases or air traversed.

Collision-waves (Dixon), "l'onde prolongie" (L
produced when 2 explosion-waves, generated sim
gaseous mixture, meet and extinguish each other,
in the direction of its originating explosion-wave.

Secondary waves, like the last three named, do n
tain them, and therefore gradually die away; they
merged as to be unrecognizable. Their velocities app
ing with the densities of the gases traversed and th
relative to the walls of the passageways.

Table 25. Velocities of Explosion-Waves

Kind of wave	C_2H_2 +
Explosion or detonation-wave	2 990
Retonation-wave	2 300

rts, at about 1 200 ft per sec, its velocity gradually decreasing to less
c in a distance of 1 300 ft.

ve, "pioneering-wave" (British), is a compression-wave or a series
ead of the flaming zone of an explosion. It makes possible the propa-
t explosion by bringing the dust into suspension.

wave of depression, is the flow of air at atmos press to fill the partial
when the expanded after-gases of an explosion cool. Depressions of
have been recorded in the Bruceton tests (43), and in a larger mine
would doubtless occur. Return-waves, being thus limited in press
nt than primary or even secondary waves, but move light objects
It is possible that in an explosion in a large mine an inward rush
entry before the heated gases cease discharging from another, pro-
es are disconnected, except in the interior of the mine.

5) **knowledge of coal-dust explosions,** as determined by
explosion disasters and at testing stations, such as the experi-
iceton, Pa:

ith a ratio of volatile combustible to fixed carbon of more than 10
in air if the percentage of ash is not too high.

nd fineness of dust. Other things being equal: the higher the per-
-combustible the more explosive is the dust; the finer the dust the
st, in presence of much fine dust, say less than 200-mesh size, dust
20-mesh may enter into the explosion; the higher the ash and mois-
ive the dust. Pittsburg coal dust, 70% passing through a 200-mesh
60% of shale dust will not ignite from a blast of 4 lb black powder;
irce of ignition the more readily will the dust ignite; thus, if a 50-foot
ust is ignited by a blast, it will in turn ignite an adjacent dust zone
tsburg coal and 60% shale, which will then propagate the explosion.
onditions, it requires 75% shale dust to prevent propagation. With
sts less shale or inert mixture will prevent ignition and propagation.

racite dust is explosive (British tests), but LOW-VOLATILE PENN-
TE DUST IS NOT EXPLOSIVE (Bureau of Mines tests), either alone or in
. This conclusion is supported by the immunity of the Penn anthra-
idespread explosions. It is not yet determined whether this is not
harder structure of the Penn anthracite. A certain variety of the
cture and volatile-combustible ratio of 10% or more, on testing would
e an explosion, but would do so in presence of 1% or more CH_4.

CH_4 in the air, in percentage below its own explosive limit, INCREASES
COAL DUST (except low-volatile anthracites). An increase of each 1%
3 to 5% or more increase in inert matter of the coal dust; hence the
anger of igniting originating dust explosions in gaseous workings.

ity of the atmosphere, even to saturation, or wet walls and floor,
IGNITION OR PROPAGATION of a dry dust explosion, for, while presence

MINE SAFETY

. Safety Organization for Mining Companies

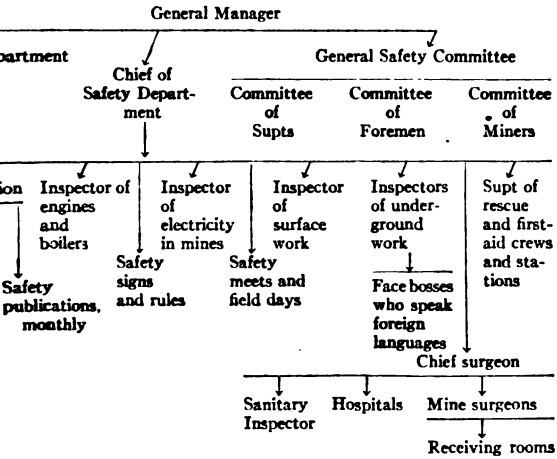
nization is essential to sound business policy, as well as on grounds.

f compensation acts by many states has greatly increased the cost of d injury claims; in some states this cost, in percentage of payroll, is 2 to ch prevailed up to 1910 (Art 24). But the compensation now goes more ed persons or needy heirs, and is not as formerly so largely consumed in l charges. Mining companies should care for widows, orphans, and in- from accidents, instead of depending, as in the past, on public charity. o is benefitted by safety improvements, since the cost of accidents must ded to selling price of product.

accidents in mines of the U S form from 60 to 75% of the total, nparison of our statistics with those of other countries, or with ds in this country. These can be lessened by inspection, educa- , and safety appliances, combined with proper organization.

f safety organization is one that is parallel to, but independent ng department.

fety Organization for Large Companies, Suggested by Author



manager, in the effort to economize in mining, transporting, and loading duct, may overlook questions of safety, and for economy or speed may unsafe machinery that should be scrapped. On the other hand, an over- anager, constantly fearing accident, becomes inefficient. But, if the ludes a competent inspector, responsible to a higher authority than the ger, and he reports a certain practice unsafe or recommends a change, the ved that he is not responsible for the cost incurred.

22. Mine Supervision and Inspection

. Mine accidents are often due to the isolation of the miners, a working place, rendering supervision difficult. While there is man with shift, timber, and other special bosses, there may be

23. Safety Meetings and Publications

tings, as an aid to increased care in prevention of mine acci-
ɔved to be of value, operating to educate miners and foremen
ɔring about more harmonious relations between employer and
e and national contests similarly serve to attract attention of
ɔovement and its importance to themselves.

ications, issued by mining companies from time to time (some-
by the safety department), do great good, because every em-
read English learns how a certain accident occurred, and how it
n prevented.

s and direction signs are useful in the prevention of accidents,
g uniform symbols, especially the red ball for danger, and the
the direction in which to go, the non-English speaking miners
what to avoid and where to go safely.

24. Mine-accident Liability Insurance

compensation acts. Until some mining states began the
hese Acts, the cost of death and injury cases from mine acci-
rally small as compared with payroll cost; widows, orphans, and
nerously treated by some companies, not by others (Sec 22, Art 8).

, coal-mine accident insurance ranged in different states from $1.50 to
d insurance was given by one cooperative company in a central state
s at 75¢ per $100 of payroll; in the same state rates now range from
100, and are quoted at $7 on coal mines in a western state that has had

ath and injury compensation costs have been similarly increased by the
ts of the respective states, but they have been effective too recently

for meeting liability arising from mine accidents has been of
lue to the operators in the past, when flat rates were given in
standard insurance companies, regardless of whether safety pre-
observed or not (Sec 22, Art 8, 9).

e of the more important accident insurance companies have proposed
lits or discounts for rating organization and for different accident-pre-
and devices, and to employ mine inspectors who will not only in-
dvice. If the plan is found commercially successful, it should greatly
rators, possibly excepting those large enough to carry their own insur-
pendent corps of inspectors. It should lead to improvements for safety,
mple, in the whole mining industry.

State Authority, Regulations, and Inspection

Each state has police power over the mines within its borders
own regulations, which unfortunately differ widely, instead of
for the same class of mines and mining conditions.

egulations have been on the statute books in the leading coal-
for many years; one of the best codes is the recently revised
nnsylvania bituminous district, including electrical regulations.

ne-fire prevention regulations, as an outcome of the Cherry mine-fire
ois regulations are the most explicit and stringent, though some fea-
ent, are impracticable if taken literally.

ng regulations in many states are neither complete nor satis-
ly the most complete is the code now adopted in California. A

1. Introduction

Character of mining laws. These laws define the for mineral deposits, establish his methods of procedu sion while searching for mines, and give him assurance conditions have been fulfilled and valuable minerals for the operation of mines, and for the safety and health jects of Federal and State legislation, but are rather in sanitation rules for the daily guidance of mine work frequent change, and are not considered here. (See

Importance of an understanding of mining la considerations:

1. There is always a prescribed course of procedure ing and perpetuating such title as is granted by the la is in the exploratory stages and after ores have been strict compliance with these statutory provisions the mines after they have been proved to be of value.

2. The peculiar apex provisions of the U S minin of the Supreme Court are of vital importance to the n where the laws apply. The titles to many mines hav or entirely forfeited by inattention to the obvious and the statutes.

3. A mining engineer, called upon to place a valuati where the apex laws are in force, must be familiar wit of apex litigation hangs over many mining investme safely recommend the purchase of a quartz (vein) mi consideration.

2. Theories Relating to Acquisition of

Principles of construction of mining laws of th in two classes: 1. That in which the State or a private has the right to grant concessions or leases to indiv discretion, or under certain general restrictions. T system. 2. That in which any individual, under speci as to nationality or color, has the right to locate on disc limited areas of ground, and under certain conditions of the same. This is the "Claim" system (Alford, p

Concession system had its origin in the rights of to the mineral products of the ground, and it prevails t all the ancient civilizations. Its advantage is that th mining rights may select its concessionaires, and thu the hands of those who are able to operate them and t taxes, or royalties. There is incidental economy in t collection of dues, and the greater stability of mining is criticised for placing unduly large powers of property few men, and for taking away from the poor prospec wealth; it is also said to destroy competition in the ordinately large profits in the hands of a few; and that of mining ground unworked, thus reducing mineral p opportunity for labor. These objections may perhaps facts that the terms of concession may and usually do of development; that they reserve to the Governm financial transactions and capitalization of the conc

f large corporations are generally conducted with greater efficiency
n both prospecting and mining stages, than those of smaller con-
viduals.

n originated in the early days of mining in the U S. Prospectors
ewly discovered gold districts of California, later to those of
to preserve public order, some arrangement became necessary
on the spot the area of ground that each man was allowed to
onditions under which he could hold and deal with it. Hence
f the discoverer to a "claim," a term now in general use in legal
re consolidation of claims is prohibited, the result is waste and
where claims are permitted to be held without systematic develop-
results to the country at large, nor to the claim holder; and it
eing "a system which, although it may appear at first sight to
idual enterprise, in reality leads to an enormous waste of both
rganized energy."

ental principles form the basis of all mining laws: 1. The right
rs to a secure and indefeasible title to their property so long as
in specified conditions, compliance with which is absolutely
n power; 2. The right of the state or other landlord to certain
or taxes on the profits of the mines, and to reasonably constant
effective work on the mines, so that capital, represented by prop-
shall not be unduly idle. These principles are essentially com-
s of all countries, though in individual cases modified to suit
gical, and physical conditions, as well as the history and theories
f the particular mining region (Alford, p 7).

ITED STATES MINING LAWS

3. Sources of the Laws

ral domain. Since nearly all of the domain in the states and

An act to modify and amend the mining
territory of Alaska was approved Aug 1, 1912

By act of Congress, Aug 24, 1912, Alas
and provision was made for a legislative assemb
the privileges of a territory, and may pass such
the federal laws, in the same manner as states
may legislate on mining subjects. An elaborat
session of its legislature, Apr 30, 1913 (Sess, La

By an act of April 20, 1915, an abstract of
30, 1913, was repealed.

Placer claims. 1. The locator of a claim shall
ment a notice containing: (*a*) Name or number of cl
of discovery and of posting notice; (*d*) Length and

2. Boundaries must be clearly defined by placing
least 3 ft above ground by 3 inches diam, hewed on
at least 3 ft high by 3 ft diam. Each post or monun
number of claim and number of corner or angle, on
monument. If location is on ground covered by b
blazed along claim lines.

3. Within 90 days after posting notice the locat
the district a certificate, containing data (*a*), (*b*), (*c*)
of the boundaries referring to some natural object, p
mining claim. Failure to record such certificate sh
claim, which is then open to relocation (with the usua
owner).

4. No individual claim shall exceed 1 320 ft in
claim shall exceed 2 640 ft in greatest length. Any
in area or length (see 5), may be relocated as to suc
that end of the claim farthest from the initial monu

on placer claim shall hereafter be located in Alaska in excess of 40
y placer claim hereafter located, and until a patent has been issued
than $100 worth of labor shall be performed or improvements made
including the year of location, for each and every 20 acres or fraction
nt work for contiguous claims under one ownership may be done as
e par 6, under Lode claims).
all locate any placer claim as attorney for another, unless he is author-
power of attorney, duly acknowledged and recorded in the district
nor may such attorney locate claims for more than one individual in
district during the same calendar month. No person shall locate, or
for himself, in any one recording district, more than 2 placer claims
onth, one or both of which may be included in association claims.
im after the annual assessment work has been done, an affidavit must
istrict recorder, not later than 90 days after the end of the calendar
work was done, setting forth: (*a*) Name and number of claims, and
) Number of days' work and kind and value of improvements made;
nance of assessment work; (*d*) Place where work was done, with ref-
undaries; (*e*) At whose instance work was done; (*f*) Actual amount
improvements and by whom paid, when not done by owner.
claim by a U S mineral surveyor may be credited to assessment work,
lit does not exceed the assessment for one year. To obtain such
eld notes must be filed in the recorder's office, with sworn voucher of

. Location notice posted upon the claim shall contain: (*a*) Name of
Name of locator; (*c*) Number of linear feet in length along center
point of discovery, with width on each side of center line, the general
being marked as near as can be determined.
upon which the location is based must be defined by the removal of
aterial to expose the discovery claimed, and in such manner as to pre-
far as practicable, from obliteration; also its locus must be witnessed
post, bearing the location notice.
ll exceed 1 500 ft along center line, nor more than 300 ft on either side
thin 30 days after posting location notice, boundaries shall be marked
stake, or the blazing of a tree, at least 3 inches diam, at each corner
the side lines. Each mark shall bear the initial of the lode or claim,
point upon the boundaries which said monument represents. Center
nes shall be marked by blazing trees or cutting brush, or erecting line
ers or angles at inaccessible points may be marked by a witness monu-

ys of the posting of location notice, a certificate (similar to that for
ante) shall be recorded with the district recorder.
ms is to be made as prescribed in the California law (Art 16). Corner
should be connected by course and distance with the nearest corner
y, or with a U S monument, if the claim lies within 2 miles of such

ment work shall be $100 worth of labor or improvements, the period
ms to begin on Jan 1 following the date of location. If the claim in-
ne location, contiguous and under one ownership, $100 worth of work
ay be done in common, provided such work benefits the entire group.
be credited as for placer claims (see *ante*). Affidavit of assessment
placer claims; with added provisos that the wages charged shall be
g in the district, and that not more than 8 hours' work per man per
d. A declaration must be made that the time and expense of travel-
claims has not been included in computing cost of assessment work.
eceive the customary fee for filing a notice of location in his district,
ch claim included above a single claim.
tion, and location of tunnel rights and millsites, may be made as pre-
fornia law (Art 16). Assessment work for tunnel sites shall be $500
vey not to be included. Assessment work for millsites shall be $25 per
clude cost of survey; or $25 cash may be paid to the Treasurer of

of mining claims. There are two classes: Lode claims and

12. Lode Claims

Under the law of 1872, lode claims may have a maximum
, and a maximum width of 600 ft, in no case exceeding 300 ft
he vein at the surface. The owner of a valid location is also
ins of which the tops or apices lie within the exterior bounda-
provided they were not adversely claimed on May 10, 1872.

title. No lode claim shall be located until after discovery of
thin the limits of the claim. Sufficient development work is
d by the department to disclose existence of a vein, and if
al course and indications that it contains valuable minerals.

ce should give the course and distance as nearly as practicable,
haft on the claim to some permanent, well-known points or
one monuments, blazed trees, confluence of streams, prominent
in the immediate vicinity; also names of adjacent claims. A
t of stones should be erected at the discovery point or shaft,
ner of the ground claimed. Notice posted at the discovery
of the lode claim, names of the locators, number of feet claimed,
on from the discovery, and whether the claim thus staked is
on one side of the discovery point. Location notice must be
required by the state or territorial laws and local miners' rules,

of possessory title to a lode claim located since May 10, 1872,
the performance of at least $100 worth of work upon it each
This work is not required after entry for patent. Failure to
ired amount of work subjects the claim to re-location, unless
his heirs, assigns, or legal representatives, have resumed work

ocation on the ground, so that its boundaries can be readily the requirements of the federal statute. This law has been most of the mining states; and the number and character of nonuments particularly specified.

tice of location is not demanded by the national law, but is the laws of all the mining states. The time allowed in which from 30 days after date of discovery to 90 days after location. is needed.

29. How Mining Rights may be Lost

a mining claim may be caused by failure of the claimant to per- acts required by the laws for maintenance of possession. On S Supreme Court has said that right of possession "may be for- ure of the locator to do the necessary amount of work; or if, several locators, he neglects to pay his share for the work one by his co-owners, his right and interest in the claim may be co-owners under the provisions of the statute." Except in re will only ensue upon the lapse of the statutory period, upon nt the claim, and upon entry and location by another." (Lind-

t likewise results in loss of mining rights. In the same case as Elkhorn Mining Co), the Supreme Court held that "his interest also be forfeited by his abandonment, with an intention to t of possession." In this connection Judge Lindley remarks: perates instanter. Where a miner gives up his claim and goes hout any intention of returning, and regardless of what may who may appropriate it, an abandonment takes place, and the to its original status as part of the unoccupied public domain." 7.) "Abandonment is always a question of intention. In ment of intent is not involved." Resumption of work in good tion of possessory rights by others operates to prevent forfeiture.

les, and ledges throughout their entire depth, the tops, or apices, of ne boundaries, the right to pursue the vein in depth outside of such imited, however; • • • •

such a patent confers the right to everything found within vertical ugh the surface boundaries; but these boundaries may be invaded by ator holding the apex of a vein under a regular valid location, in the on its downward course underneath the patented surface (Lindley,

onveys to the patentee everything within vertical planes drawn down-surface boundaries, EXCEPT: 1, such lodes or veins whose tops or he placer limits, whose existence was known prior to the filing of the cer patent, and were not included in the placer application; 2, such aving their tops or apices elsewhere, as may underlie the placer sur-ay lawfully be taken by the apex lode locator under a regular valid uing his vein on its downward course. In the last class of cases the of location is wholly unimportant (Lindley, p 1 915).

33. Extralateral Right

gin. The right given by the mining laws of the U S to follow the surface of land owned by another was aptly termed the ht" in an early discussion by Dr. R. W. Raymond (*Trans* p 387), and has passed into current use in legal phraseology. the law has given rise to interminable litigation; and in its olumes of opinions have been furnished by the courts and oks. The manner of its introduction into our system of laws be clearly understood. It is at variance with the ordinary ican codes, and is not to be found in mining laws of any country was tried for a long period by the Germans in the sixteenth and uries, where a sort of inclined location was allowed, the miner not only to follow the vein beneath the surface, but having also 5 or 30 ft) on each side of the vein, parallel to its walls, within R. W. Raymond, "Mineral Resources," 1869, p 195); but it oned because it gave rise to so much litigation. It was later ime in British Columbia, but promptly given up, for the same lark, *Trans* A I M E, Vol 43, p 617.) It may have arisen from laws resulted from the local rules of the miners, and that these luct of the evolution and development of the western mines, ace rights only, and at first solely with reference to placers, an

lines. The planes of the end lines, drop
extended in their own direction until they
vein, bound the extralateral rights on such
ideal location is the exception rather tha
rule. Such conditions result from the ina
of the locator to determine the actual cou
strike of the vein at the time of completi
location. As a matter of fact, the locato
mining claim usually judges such course or
from a small portion of the vein disclosed
place of discovery. It is almost impossible
termine correctly the true course or strik
vein from such a small exposure. Veins are
ular in their course or strike, and may be
running through the earth in almost every
ceivable direction.

Principles of extralateral rights. The
cation of the law of extralateral rights, a
vided for by the Act, to the varied cond
which have presented themselves, dependi
the course or strike of the vein within th
face boundaries of the location, and the fo
shape of the location itself, has been the
of prolific litigation in the mining regions o
certain well-established principles must al

* Fig 1 to 10 reproduced by permission fr

of extralateral rights is the EXISTENCE OF THE APEX of vein within es of the location, dropped downward perpendicularly and there- along the vein should always be limited by the extent of the apex . This is recognized by the Supreme Court of the U S in Del Co *vs* Last Chance Mining Co (U S, 55) in which the court says:

e in mind in considering the questions presented, that we are dealing ory rights. There is no showing of any local customs or rules affecting in and prescribed by the statute, and beyond the terms of the statute, . They have no power of legislation. They can not assume the exis- al equity, and rule that by reason of such equity a party may follow a ory of his neighbor and appropriate it to his own use. If cases arise has made no provision, the courts can not supply the defect. Congress he conditions upon which extralateral rights may be acquired, a party within those conditions, or else be content with simply the mineral e of his territory. It is undoubtedly true that the primary thought of sposal of the mines and minerals, and in the interpretation of the statute se must be recognized and given effect. Hence, whenever a party has the ground within whose surface area is the apex of a vein, with a few its course or strike, a right to follow that vein on its dip for the same awarded to him if it can be done, and only if it can be done under any nstruction of the language of the statute. If the surface of the ground el, and veins constantly pursued a straight line, there would be little ion to provide for all contingencies; but mineral is apt to be found in as where great irregularity of surface exists, and the course or strike egular as the surface, so that many cases may arise in which statutory o secure to a discoverer of a vein such an amount thereof as equitably ught to receive.

at extralateral rights exist in any location, its END LINES MUST c 2 320, U S Rev Stats, Iron Silver Mg Co, *vs* Elgin Mg Co, It is not held that the end lines of a mining location must be that such location be valid, but only that they must be par- give extralateral rights to any vein, the apex of which may lie ce boundaries A prospector ight to make uch shape as will be held herwise com- . STANFORD LIBRARIES

The only method whereby the subject of e
discussed is by considering the various conditio
and applying the law to each condition.

1. **Ideal location.** When apex of a vein c
end lines of a location, which are parallel to e
to such vein are clearly defined by the statute,
planes of the end lines of the claim, extended
intersect the exterior portions of the vein. T
trated in Fig 1 and 2, and needs no further co

2. **Outcrop cutting both side lines.** W
passes through both side lines of a location, wh

can exist, because the end lines are not parall
much of the vein on its dip as he has length o
lines. If the apex of a vein within the boun
number of feet in length, equitably the
owner of such location should be given
the same number of feet on the strike of
the vein extralaterally, at any depth, and
no more (33 Mont, 46). See Fig 5.

4. **Outcrop cutting two converging boundaries.** Where the apex of a vein crosses two boundaries of a location which converge toward each other in the direction of the dip of the vein, it has been held, in the case of Carson City Gold Mining Co vs North Star Mining Co (86 Fed, 658), that the extralateral rights would exist, bounded by the vertical planes of the end lines, projected in their own direction this point Judge Lindley states:

Fig

Fig

There can be little doubt that extralateral rights or patents issued under either Act where the end din of the vein, giving the locator or patentee less in

however, that the decisions of the highest courts are not yet question, and some lower courts have held the contrary of the herein. This case is shown in Fig 6.

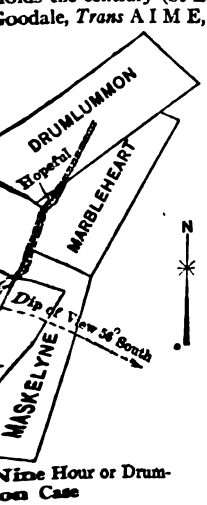
tting end and side line. ering and leaving through same side line. Where apex ourse enters and departs from the claim through the same Supreme Court of Colo has held that no extralateral rights Olds, 23 Colo, 433). The U S Court of Appeals for the Ninth olds the contrary (St Louis Mg Co *vs* Montana Mg Co, 104 Goodale, *Trans* A I M E, Feb, 1914).



Nine Hour or Drumon Case

The extent of extralateral rights on a vein in a case such as that last referred to presented an interesting question. The vein in controversy was a wide one, entering and departing from the St Louis claim, at an acute angle, through the same side line. At the point of departure from the St Louis claim, the apex of the vein was conceded to be 25 ft wide, measured along the boundary which it crossed. The St Louis claim was conceded to be the prior location, and the owner thereof claimed that it was, therefore, entitled to all extralateral rights on the vein, so long as any portion of its apex remained within the boundaries of the claim. The Court of Appeals upheld this contention, saying:

> The only deduction which can be made from the foregoing rules is that, inasmuch authority permits a division of the crossing portion of the vein, hority favors the senior locator, the entire vein must be considered or location until it has wholly passed beyond its side line.

his condition, showing properties in conflict in St Louis case

on, Geology, Maps, Equipment, Accounts, and Reports

Distance from sources of SUPPLIES and from the MARKET for
o cost per unit, safety and reliability of existing means of TRANS-
oe ascertained. If transport improvements are essential or de-
oncerning means, costs, and advantages should be secured.

ng much high-grade ore have been successful in unfavorable locations and
eans of transport, as, for example, the backs of men; but hard-rock,
ties (the output of which has a gross value of say $5 per ton of crude ore)
ly when on rail or water transport lines. Difficulty of access to the
he FINANCIAL CENTER furnishing development capital may sometimes
ent of small or low-grade deposits. Location with respect to supply of
nd FUEL, or of HYDRO-ELECTRIC POWER, is of prime importance, and if
e are lacking, the cost of supplying them should be at least roughly esti-
E and its effect on operation of the property should be noted. Nature
ENT of the country in which the property is located is important, if there
its stability or ability and inclination to give proper protection to in-
cy to levy excessive taxation, to pass restrictive laws, or to obstruct
property by permitting illegitimate interference should be considered.

gy is studied for the light it may throw upon the probability of
sence of economic quantities and values of the minerals sought,
ion of exposed values to quantity of assured mineral (Art 11),
able persistence laterally and in depth of values and character-
evealed, and upon the best methods of exploitation.

itches, pinches, stratifications, and other rock characteristics, faults, horses,
condary enrichments of possible influence (Sec 2), should be considered in
e amount of ore proved by existing or likely to be proved by proposed
hese data, particularly when scanty, should be supplemented by similar in-
ing neighboring properties or districts; especially those having the same
f similar character with different values. Government or private geologi-
orts of the property and district, or of neighboring properties or districts,
igated for such information. U S Geol Surv folios, which include topo-
ological maps, geological sections, and descriptive matter, are valuable.
by writing the Survey office, Washington, D C, ordering by number as in
losing price in currency or P O order, payable to Director of the Survey.
o 1 to 184 inclusive, have been damaged by fire but are entirely usable.

ologizing should be undertaken so far as is likely to throw light
f the property, with expenditure of available time and money.
ude a thorough examination of surface and underground ex-
udy of existing drilling records or cores (Sec 9). Character and
l rocks, and of the deposits themselves, should be considered as
ce in determining the best method of exploitation.

Method and cost of working flat-lying seams, as many coals, clays, and
may be influenced by the strength and permeability of roof and floor.
, and relation to topography of the overburden of flat-lying secondary
the copper porphyries, determine the utility of the caving system of
removal of overburden and open-cut work (Sec 10). The workability
sit by dredging, hydraulicking, ground sluicing, or drift mining, is de-
as much by the character, condition, and slope of bedrock, occurrence,
ize of boulders, and depth and character of overburden as by the engi-
of quantity and head of water and debris disposal (Sec 10).

ine, property, and general topography, both private and
ould all be investigated and their reliability determined (a- f--

erratic values are present. Under prescribed conditions proper crushing y using a screen as is done by the U S Bureau of Mines, which provides a n with its coal-mine sampling outfit. But trained observation can deter- te the suitable size with sufficient accuracy (see also Sec 31, Art 2, 3).

l quartering (see also Sec 29, Art 3). The crushed mass is cone by shoveling all the material to one point on the quartering manner that the particles roll down in all directions from the Irregularities in composition of the mass are thus distributed ayers of a cone. The top of the cone is then flattened with the ovel, by spreading the material equally in all directions until a ned, the thickness being about 0.1 the diam. This disk is marked , and the diagonally opposite quarters are cut out, care being material in the rejected quadrants is removed, but no other. contains half the original quantity and, after reducing the large onally, coning and quartering are repeated, thus securing one- original. The cycle of crushing, coning, and quartering, is re- ne sample is of the desired size. With sufficient care that the e up of layers of each shovelful, evenly distributed about a fixed at the cones are flattened by being worked out evenly from the rections (coning about a fixed vertical rod (12) insures accuracy ts), results of any desired accuracy are obtained, provided suffi- s done either before or during the process.

mple is corrosive, the best quartering floor is a piece of boiler plate, large the disk of material prepared for the first quartering. When available, t shaft landings make good quartering floors. A well-laid floor, prefer- od, is the next best. When neither are available, a platform may be oards as solidly and evenly as possible on the ground and covering them sheet. Cloth covering is harder to keep free from residual fines than a or, but thorough brushing with a whisk, or scrub brush, usually suffices, elds better results than when working on a floor containing cracks in dge and be lost or inopportunely reappear. The whole process, includ- s often referred to as quartering.

hen using a sheet in reducing lots of 100 lb or less, time is saved ad of coning. It consists of mixing the mass by drawing one heet forward towards the diagonally opposite corner, until the en rolled over and over on itself to the limit of the capacity of e first corner being laid back in place and the diagonally oppo- ed over the sample, the process is reversed, and so back and terial then being left in a long mass across the center of the done at right angles to it, by working with the other diagonally of the sheet.

two rolls each back and forth with each set of corners, give good mixing ready for final rolling into the center by all four corners preparatory to ing may be imperfect unless the folded-over corner of the sheet is held is pulled forward; otherwise the material may slide on the sheet instead er on itself. Also, if the mass is wet and sticky it will adhere to the ing will be imperfect.

Decimating, Trench, Pit, Drill, Small-parcel, Dump, and Large-scale Sampling

he reduction of a mass by some type of splitter, or series of which alternately retain and reject a series of equally broad stream of crushed material poured over them (Sec 30, Art 3).

ng, the chips must be so broken as to represent equal distances by equal roper proportion of fines and coarse must be secured from each point of e number and size of chips determined in accordance with the irregu- posure.

les are taken by "grabbing" pieces at random. Information haracteristics can thus be gained quickly, and by careful adap- val sampling a method of some precision is developed.

dump surface, for example, may be determined with as much accuracy aking the "grabs" at regular and closely-spaced intervals, securing at roper proportion of coarse and fines.

7. Underground and Placer Sampling

d mineral exposures are usually best sampled by interval-channel- (Art 6). As stated, deposits the values of which are largely in r very rich minerals can not be sampled and assayed in the usual e-scale sampling followed by mill or smelter runs is requisite. st always be checked against previous operating records and a te of value based on careful inspection of ore exposures. In dertaking any sampling, the peculiarities of the deposit should as far as possible by such inspection. For this purpose fresh d be made at frequent intervals, by breaking off pieces with a gh material, with moil and hammer.

ue will be saved, and the engineer's efficiency increased, if this work be od hammermen, at points indicated by the engineer, who is thus left to attention to studying the exposures. The sample interval is usually 5 bly 5 ft, which is short enough to afford means of check by calculating s on alternate samples. Precious-metal deposits should be studied care- eaks and chutes, and sample interval made short enough to include all h or low values. In case of streaks, it is often desirable to divide the e banding into two or more samples, to insure proper proportioning and to exclude (when revealed by assay) low-grade or barren streaks in subsequent mining they could be left untouched (Art 6).

pling must be done in a manner to show much smaller values ered in solid deposits. Large-scale dredging, favorably located, American or Yuba rivers, Cal, gives high percentage of recovery ut 5¢ per cu yd, and in such cases 10¢ ground is profitable when icient to keep a dredge at work for a number of years (Sec 10).

e conditions (properly sloping bedrock, abundant water under sufficient dump room) (Sec 10) hydraulic mining costs even less than dredging. etween 7¢ and 10¢ per ton (0.0035 to 0.005 mg per assay ton, or about assayer can report with any assurance of accuracy), but placer samples he nearest 0.1¢ and averages calculated to nearest 0.01¢. For this the ured and concentrated by rocking and panning before being assayed. s of a practical rocker (11).

mining amount, condition (whether coarse or fine), grade and the gold, other features should be noted at time of sampling. is to be dredged, it is desirable that the gravel (material up to s head) be free from boulders. are the best method of permanently recording sampling results,
e results in relation to each other and to the property as a whole,
ng this data in a report. They are made by tracing a map of
ing the sample positions thereon by dot or line, and writing the
or value of each sample alongside its location (Sec 19, Art 1).

ingle value for each sample, the scale of 1 in = 50 ft is as satisfactory for
r most other work. If several constituents are to be entered for each
1 in = 20 ft is preferable. If several entries per sample are necessary,
ale maps are available (1 in = 50 ft or smaller), the sample number
ten at the point of location, and a table of all data desired placed in a
sheet. This is not so good as the direct entry of the data at the loca-
tion in value in the different workings is less obvious. Variations in
e element, or currency values of several elements, are sometimes indi-
y of shading, variety in coloring, or design symbols, the fluctuations
at a glance. This method has gained favor on the Rand.

ssays, assay maps should show the tonnage calculation blocks,
l average values. For steeply-dipping deposits, these blocks
on longitudinal elevations or on slope plans. For flat deposits,
nstructive.

9. Salting

process of intentionally or unintentionally raising the value of a
at of the exposure sampled, must be continually guarded against.
of intentional salting being attempted must be borne in mind
mstances seem to give little occasion for it.

engineer examining a copper mine, taken on operating lease with privi-
ecommended that the smelter be operated on average ore to be obtained
f uniform thickness from the floor of each level. The mine foreman,
l all the ore for the test run from a particularly rich lot which he knew
or of one of the levels and, in absence of the engineer (who had been
the single examination), the lessees received the impression from the
at workings actually averaging 3% contained between 4 and 5% cop-
n had no connection with the owners of the property, was solely the

10. Sampling Checks and Conclusions

accuracy of both sampling and assaying should be made in suffi- to give assurance that results are as reliable as circumstances e desirable. When possible, ERRATIC SAMPLES should be retaken precaution against inaccuracy or contamination. When assays de prior to leaving the property, it is well to duplicate 5 or 10% g, selecting the samples for duplication at random, but so as to which appear to be of high, low or average value.

uld be checked by sending for assay a small percentage of duplicates last reduction in sample preparation), and a few blanks of known barren w numbering. Also, a few duplicates should be sent to a different assayer. lways agree in detail, but the average of the duplicates by either assayer from that of their originals by more than a small percentage of the values vided the assaying is accurate, the DUPLICATE SAMPLING should check in r; that is, actual duplicates may vary considerably, but the average of riginals should show reasonable agreement. If sampling has been done rval, compared to the total length of exposure (say 5 or 10 ft on large ge of alternate samples should closely agree with that of the intervening ater the number of samples, the closer should averages agree.

from results of sampling should be based upon propor- s; that is, the quantity of material represented by an assay ich a factor in calculating an average as is the assay itself. Thus, d vein, exposed over its full width and sampled at regular inter- y is multiplied by the sample width, and the sum of the prod- the sum of the widths to determine the true average. If sample regular, the width is first multiplied by the interval to the suc- (using the last interval on both the last and next to last sample) ict multiplied by the assay. The sum of the interval-width- divided by the sum of the interval-width products then gives d average.

exposures containing large and irregular proportions of heavy minerals (as galena in quartz), a SPECIFIC-GRAVITY DETERMINATION is sometimes mple, and the interval-width product multiplied by it before multiplying he sum of the interval-width-gravity-assay products divided by the sum dth-gravity products then gives an average assay, which includes allow- ific gravities of different parts of the ore exposure. This refinement is are rare in which the engineer's knowledge of the mining value of the sufficiently increased by gravity determinations to justify the added he value usually follows the heavy mineral, the probable effect is to assay. This, unless subsequently discounted, seems more likely to decrease error in determining the mining value. Owing in part to the re of the valuable minerals, and particularly to the inevitable inclusion, some of adjacent low-grade or barren material (which can not properly sample), the yield per ton of a carefully sampled deposit is generally alculated average, and the tonnage higher. An allowance (say 10%) e made for this in reporting values.

sometimes taken against over-valuation is the ELIMINATION ATIC VALUES, substituting for them the average of the two ad- but this practice is questionable. If there are enough erratic the result seriously, there may also be enough high values to n of all. The proper disposition of erratic samples calls for each case, and for the engineer's best judgment.

12. Prospective Values, Percentage o

Prospective quantities and values. trained judgment than, and is of as much vi part of an engineer's report. Having coll yield and present showing of values, geologi occur and records of similar conditions and careful sifting, balancing, and digestion of form as definite an opinion of the prospe opinion in practical form, the engineer may questions: 1. What are the geological ar change of formation, well-determined fau

itions), and to what extent do these preclude possibility or prob-
er development of values in depth or horizontal extent? 2. Are
ly probable continuations or indications of independent values
y? If so, what is the least development and cost which will
nformation regarding such values, and what development and
ry to prove thoroughly these values, or prove them sufficiently
profitable industry thereon? 3. In addition to highly probable
opes may reasonably be entertained as to extent and value of
ineral resources of the property, what scale of outlay is likely
and justified, and what, if any, definite limitations do local
e on such hopes? In general, deposits not definitely limited
ntain at least 25 to 100% more ore than can be actually assured.

(Question 1) A deposit was limited at one end by a property line across
dy passed to an adjoining mine, while the structural geology showed
main workings bottomed in and were limited by a synclinal trough.
mparatively small outlying developments on what could be traced as
an anticlinal fold succeeding the syncline, exposed a small but excellent
lower level than the bottom of the syncline. The property being in
and equipped for diamond drilling, $1 000 spent in boring in the floor
e was likely to add many times this amount to the value of assured ore
on 3) The drilling was also likely to trace ore to sufficient depth to
winze, so as to render a new level acccessible to drilling. The winze,
at the lower level, would cost $5 000. Granting the first favorable dia-
ng, the general features of the deposit and the reputation of the district
pe that enough ore could be proved and indicated to justify opening this
direct from the surface (replacing the long crosscuts and hoisting winzes
revious development had been made) by an efficient main shaft to cost
This shaft in operation, a low-grade outlying deposit on the strike
as hope, because of the 25 to 50% increase in value with the depth of
developed) could readily be proved and exploited in depth. This
e proved valuable, in addition to the main deposit, the mine would have
eat future, notwithstanding the limitations of property line and fold
nce the mine was equipped and in profitable operation, its purchase at

A thoroughly proved gold placer deposit in successful operation by te of 1 000 000 cu yd per year, at cost of 6¢ per cu yd, contained 10 000 000 ing 13¢ per cu yd recovery value. Annual operating profit was therefore he life 10 yr. Table 5 shows that an income having a 10-yr life will yield esides a sufficient amortization charge, accumulated at 4%), when the in- ich a sum that the annual dividend is between 13 and 14% thereon (in posite to "10.3 to 9.4 yr" in column 2, will be found "13 to 14%)." To turn the dividend rate must be between 18 and 19%. Dividing $70 000 by d 19 respectively, shows that the property will yield 5% net, besides amor- ween $500 000 and $538 000 is paid for it, or about 10%, at a cost between $389 000.

e of assured mineral reserves, the whole question of value is one of d amortization tables have little application. But, when part of 's value lies in assured mineral, it is often instructive to carry out ation idea as far as possible on the assured reserves; and then rs of work, tons of ore, etc, required beyond the reserves to return n placed upon the property with appropriate profit.

A copper mine, having assured reserves of 750 000 tons ore yielding, at per ton profit, is operating at rate of 150 000 ton per annum, and its secu- pen market at a price aggregating $2 000 000. At the annual profit of yield is 15%. Assured life, 5 yr. Table 5 shows that a 15% dividend 3.6 yr to amortize the principal, if 5% per annum return is to be had, or sk is such that a net 10% return is required. The $2 000 000 market valua- roperty therefore assumes a life beyond the assured reserves of between a sufficient rise in the aver price of copper above 14¢, or a combination of e additional ore required, independent of change in price of copper, would 2 250 000 tons. At an aver ore yield of 2 000 tons per ft of depth, these s would involve the continuation of the deposit with average strength for h of 270 and 1 125 ft, respectively.

on of Mines Having No Assured Mineral, or in which the Assured Mineral is of Unproved Value

nines of this kind is simply an attempt to discount the future, and almost entirely a matter of personal judgment. A great variety nd conclusion, according to temperament and viewpoint of the st be expected. But the engineer should not make this an excuse give his client the benefit of his best judgment on this vital ques- tements in Art 12 as to prospective values and quantities apply qual force. All possible information should be secured regarding in question, neighboring properties and their relative location, the neral, and results secured elsewhere from apparently similar prop- strength and character of outcrop; extent of, and values shown ound development and drill records or cores; apparent tendency pinch or swell, to become enriched or impoverished, or to assume nore complex character with depth or with horizontal extent; like- ling a feasible treatment process, and the total values per ton in mass, whether known to be recoverable or not, should all have ching an opinion.

ogical conditions should be considered, as to whether they are favorable to of quantity and value, or the reverse; and also respecting their similarity cessful properties elsewhere. As to geographical location, see Art 2. ints having been studied and digested, the engineer should allow himself d by his general opinion, or his instinctive feeling in the matter. Analysis this opinion should be worked out and recorded, to enable the engineer to fend his position to others and steady his own resolve during periods of certainty in subsequent developments. But an instinctive sense of con- developed by exhaustive study and restrained by realization of its li

tions, is of great value to the client; it should be cultiv
strength rather than suppressed as a weakness.

Example I. An enrichment of a highly acid rock
was exposed by underground workings, near the cent
about 500 000 tons of ore. Property included an are
about 0.75 mile wide by 1.5 mile long, generally iron
of value similar to that of the proved ore was revealed
of a few hundred ft depth or less had been sunk. Bott
and the main shaft sunk below it showed distinct tende
and the workings as a whole showed an enriched zone
about the same thickness of leached overburden. T
dike was noted in one side of the underground working
dike in connection with showings of value elsewhere on
be found, discouraged the theory that the dike was the

of the values quite near the surface suggested cheap
from the surface, and the rock being both hard and ba
promised to be best. Judging by the thickness and
the exposed enrichment zone, probably millions of ton
But, the assured ore was too poor for profitable oper
and none of the outlying shafts promised that further d
richer ore. The further objection had to be met that
richer deposits of same character doubted the possibili
grade. Altogether the property could be given no
been achieved elsewhere on even poorer ore (though
ally) by large-scale work employing extensive equipm
promise of vast tonnage provable by drilling, at a fracti
an attractive feature. If successful treatment could
justification for venturing the comparatively small am
the tonnage required to justify capitalization for large
consideration with another, the engineer was finally co
certainties, the chance of large profit was sufficiently g
attractive venture. The client was so advised, but t
mately be required was not available. The engineer
devote available funds to investigating processes, to p
tonnage development by drilling, to meeting the con
of the property, to interesting heavy financial interests,
which would give such independence of position as wo
final negotiations for the transfer of the property to stro
8 years elapsed between the forming of a small compar
of regular dividends. But in half that time the client
vestment from sale of part of the securities received o
financial interests, and, the property becoming a mark
were eventually valued at a much greater amount.

Example II. A gold placer property on a small stre
the stream by property lines, while outcrops and drill
the bedrock cut off the gravel on each side. Records
experienced placer prospector, showed yardage and va
ing profit of several times the cost of a dredging
engineer was responsible for the drilling, the records
there were too few holes, and they had been placed too
if correctly drilled and recorded. Value calculations
conclusive, but indicative only. The likelihood that t
ing was emphasized, however, by the fact that the v
dredged, while drift-mining had been done above. As
a leading builder for a well-designed dredge, which
direct and cheapest mode of checking the drill records
operations. Meanwhile the property had no proved
enterprise could scarcely be considered a good gambl
The client (owner of a minority interest) was therefo

only on the basis of a very limited valuation of the property, and then speculation and in case satisfactory assurance could be given of proper perating of the company. These conditions could not be fulfilled and, as d advised was probable, a receivership and ultimate sale of the property avoid losing his original investment the client bid in the property at a cost of the dredge. Sufficient value was ultimately proved to cover the lus a reasonable profit, but only a trifle of the original hopes of the enter- ed, and only those willing to contribute to the purchase at the receiver's al loss.

Conduct of Examinations and Outfit Required

ies. All information furnished by the client (which may range tatement respecting location and supposed value of the property, d maps by skilled engineers) is reviewed, to gain an idea of the aracter of the examination, and the time and facilities required to e extent of development of the property, especially that of the ex- eral values, largely determines the time and equipment necessary and the importance of sampling results in reaching a valuation.

ation and accessibility from the engineer's headquarters depend the time uired to reach and return from the property. Technical periodicals and d books on economic geology, sometimes yield useful information, through ecial mining indices. The relations of the client to the property are usu- ee access is taken for granted; if not, the limitations must be understood f the promised report restricted accordingly. If any considerable outlay ain access to underground workings, the question of providing for this nderstood.

nination, regardless of time or money, would be one made wholly eer personally, who would thereby become thoroughly familiar tions affecting the problem. But reports must be made within a ne, and are generally needed as quickly as possible. Moreover, engineer is too expensive a man to devote time to unimportant ome assistance is always required, if only for clearing out old case of a large, operating property, the whole mineral exposure t be sampled, and its records and operations reviewed, a corps necessary for preparing a reliable report with reasonable outlay of ey.

must be selected with great care. Their integrity must be be- n, the capacities of each well understood, and none should be sponsibility that he is not well able to carry.

hould be given work that is new to him only under supervision of an ex- ior. Bright young technical graduates make excellent raw material to g, surveying, drafting, and similar work. But an inexperienced graduate sent into the field alone, except to gather preliminary information, his checked by an experienced man before any important decision is reached.

As this is usually the most tedious part of the examination it run promptly; though not until enough information has been ably by inspecting the mineral exposures) to determine if the gh sampling is justified.

ained assistant is required, he usually does the sampling, thus allowing devote his time to more general investigations. For extensive sampling ay himself require trained assistance, or at least unskilled help. 2. Operating Formulas

f carriers. For a system operating a continuous series of carriers,

t = time interval between carriers, sec
d = distance between carriers, ft
l = load in one carrier, lb
s = number of tons (2 000 lb) to be carried per hr
v = velocity of tramway, ft per min

$2\,000 \div 3\,600 =$ lb per sec to be carried by tramway, and this l, gives time interval in sec, reducing to,

$$t = 1.8\,l \div v. \tag{25}$$

ween carriers is, $d = tv \div 60$, reducing to,

$$d = 0.03\,lv \div v. \tag{26}$$

n traction rope. Tension in a rope holding any body at rest on eglecting friction, is $T = W \sin \alpha$. Friction of a body moving on $F = fW \cos \alpha$; in which,

T = tension parallel to the plane, in same unit as W
W = total weight of bodies on the plane, preferably in lb
α = inclination of plane
f = coefficient of friction
F = total friction, in same unit as W

body extends whole length of incline, as a rope lying on it, then is $W = wL$, where

w = weight per ft, in same unit as W, preferably in lb
L = inclined length of the plane, ft

this value of W in general equations for T and F above, gives:

$$T = wL \sin \alpha = wV \tag{27}$$

$$F = fwL \cos \alpha = fwH \tag{28}$$

V = vertical distance between ends of plane, ft
H = horizontal length of plane, ft

traction rope of a double-rope tramway, or in endless rope of tramway, at its upper end, taking friction into account, will be:

$$T = wV \pm fwH \tag{29}$$

erm is + when rope is being pulled up the incline and − when it own. If rope be empty, w is the weight per ft of rope alone; but attached to it, w must be increased by weight of the carriers uniouted over whole length of incline, or else the effect of carriers ulated separately and added to value of T.

3. Transmission of Power by Band Drives

sion is applicable to any type of band or rope drive, or to band tension is known.

rive, tension on slack side must bear a certain relation to tension on taut p sufficient friction to prevent slipping. The formula for this relation, l mechanics, is: $T = Se^{f\pi\alpha}$

in which: T = tension on taut side } Bot

DOUBLE-ROPE TRAMWAYS

4. General Considerations

A double-rope tramway consists of: 1, two track cables stretched
nsion; 2, an endless traction rope for moving the loads; 3, numer-
or the loads, each fitted with carriage or trolley to run on track
amp or grip for seizing traction rope; 4, a station at each end to
trol the traction rope and provide places for loading and unloading
termediate towers for supporting track cable and traction rope.
n, each load is placed in a carrier while standing on a track in
ial; the carrier is then fastened to traction rope, and is hauled
k cable to discharge terminal; there it is released from traction
ents are discharged. Empty carrier is then fastened to traction
side and is hauled back to loading terminal.

Economical limits of capacity for double-rope tramways are ap-
o tons per hr as minimum, and 100 tons per hr as maximum.
tons per hr is to be carried, it is more economical to operate the
hours or on alternate days, than to reduce its carrying capacity.
o tons per hr requires quite heavy loads at frequent intervals, and
ut the maximum that track cables will stand without excessive wear.

is seldom wise to use double-rope tramways for distances less
because terminal machinery costs as much as for a longer line
first cost excessive. Maximum limit, under favorable conditions,
es; the resulting 8 miles of traction rope is as long as can be
ssfully. If distance be greater, a series of tandem tramways can
the carriers switched from one to another; but each division is
independent tramway. Thus, a tramway at Chilecito, Argentine,
comprises 8 divisions. In any tramway, the track cables are
ections of 3 000 to 5 000 ft each, one end of each section being
tension weights attached to the other end. The carriers pass
rage and tension stations without interruption, so lengths of cables
peration nor possible length of line or division.

t weights of 500 and 1 500 lb are the usual lower and upper
s on ordinary tramways; below 500 lb there is no saving in cost
d over 1 500 lb the wear on cables is great. The time interval
rs is conveniently about ½ min. Then, 1 500 lb every ½ min =
, and is near the maximum capacity of double-rope tramways.
vorable profile conditions, 2 000-lb net loads can be carried, and
time interval can be cut down to ¼ min, but it is seldom feasible
val and increase load at same time.

5. Tramway Surveys

Table 5. Relations of Cable Sizes, Loads,

Tons per hr	Diam of cables, in		Net loads, lb
	Loaded side	Empty side	
8 to 20	1	¾	500
15 to 40	1¼	⅝	600
25 to 50	1¼	¾	800
30 to 60	1¾	¾	1 200
40 to 75	1½	1	1 500
50 to 100	1¾	1	2 000

* For lines carry ing 25 to 50 tons and for 50 to 100 tons, lengths in small for lines over 2 miles long, where driving mach for lines that carry bulky material requiring large carriers.

binations are based upon the fact that the size of load for a given ermines the number of carriers on the line; if load be small, the g stock is increased, due to the number of carriers, since part of unit is constant; if load be large, the size of track cable increases n to the individual weight carried, although the loads may be few The empirical rule used in Table 5 to determine SIZE OF TRACK allow 1 sq in of cross-section for each 1 600 lb gross weight of one allowance is decreased a little on smaller sizes and increased a larger. The GAGE (distance apart of track cables) may be 6 ft riers, but must be 8 ft for large ones, and in some cases may need Though varied to suit unusual conditions, bulky materials, or special interrelations apply to all ordinary cases.

speeds have constantly increased. Speed must be high to carry e without increasing weight of moving parts, nor the stresses due ht, but when speed is too high it is difficult to handle the carriers The practical speed is about 8 ft per sec, with 10 ft per sec as ith favorable conditions and careful designing; equivalent to 480 er min respectively.

e a typical profile on which is to be constructed a tramway to carry 60 000 lb r hr, weighing 100 lb per cu ft. By Table 5, the cables will be 1¼ and e carrier capacity will be 800 lb or 8 cu ft each, and gage will be 6 ft. If n at 480 ft per min, the spacing of carriers will be (Eq 25 and 26): time $.8\,l + s = 1.8 \times 800 + 30 = 48$ sec, and distance apart $d = tv + 60 = 48 \times$ 4 ft. The weight of an 8-cu ft bucket (Fig 17) is 420 lb, making gross loaded carrier = 420 + 800 = 1 220 lb.

the line. The profile is plotted to a natural scale, say 1 in = 40 ft " profile paper, 20 in wide, ruled 4 by 20 lines to the inch. If differ- tion between ends of line be great, several strips may be joined to- required width. If line is too long to be operated as one division points are determined and each division is laid out as a separate ne junction stations are designed (Art 17).

n of the profile, points where a rope stretched from one terminal to the st touch the ground can be seen; in Fig 11, these will be at Sta 21 and r. Sta.

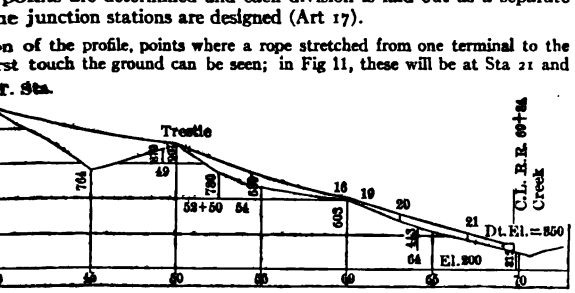

Fig 11 (Cont'd) Profile of Typical Double-rope Tramway

le is then tacked to a long table, exposing one portion of the line, say from al to the first high point; and the terminal structure is plotted in outline the conditions imposed (Art 16). A pin is set in the terminal at point ves the horizontal rail, another pin is set at the minimum height of tower ay 12 ft if snow does not lie there over 3 ft deep); a silk thread is looped assed around the other and led over the edge of the table where the spool's having been taken in thread to prevent unwinding) draws it tight. If er be ruled in green, and red thread used, there will be no confusion with ncil lines that may be added. The thread represents a chord, from which can be plotted by laying off deflections at as many points as are necessary.

= weight of moving terminal machinery in lb, and v = velocity of min.

Eq 36 and 37, gives total power of tramway as

$$\text{H p} = \left(\frac{T-S}{33\,000} \pm 0.000\,000\,1\,W\right) v \qquad (38)$$

t instant of starting, inertia of the line is to be overcome, and ance is higher than when line is running. To insure sufficient r, the following empirical rule may be used: in determining the ed by a gravity line in starting, divide l by 2; or for the power art a power-driven line, multiply l by 2, before substituting it in

ght may be carried on a tramway. This at times increases tension on ndition which must be taken into account in power calculations. On a siderable up freight can be carried when line is running at full capacity oads, but to carry up freight when there is little descending material, ery must be supplied, for use at such times.

q 36 and 38, T and S must be known. But when a drive is first these factors are unknown, since each is composed of the stresses lus half the tension weight, the amount of which has not yet been however, as half the tension weight is applied to each side, the S) will be equal to the difference of the stresses on the two sides ds, as determined by Eq 29, without considering tension weight.

eight. A sheave which will furnish friction necessary to drive or action rope is found by Eq 31, by substituting the value of $(T - S)$ the values of f and n suitable for the friction surface, and number nder consideration, and then solving for S, the tension on slack less than the tension for this side as found by Eq 29, no tension e applied by sliding sheave to provide the necessary friction. r than the tension on empty side, the deficiency must be supplied veight equal to twice this difference, applied to a sliding sheave. ations may indicate several possible types of drive with their re- on weights, and the merits of each can be considered. If S be ension produced by loads on slack side, a sliding sheave is needed e up slack in traction rope, and the weight applied need be suf- keep the rope taut near sheave. If the resulting tension, after t is added, is greater than necessary, it shows that the power ble of doing more than is required. Having found the weight to sliding sheave, T can be found by adding h_w to tension on taut ne loads as found by Eq 29. This is the stress that finally de- f traction rope required.

f these principles to the typical tramway, Fig 11, illustrates method of Fixed data for this line are:

Weight of load = l = 800 lb
Weight of carrier = e = 420 lb
Spacing of carriers = d = 384 ft
Weight of traction rope = r = 0.89 lb per ft
Horizontal length of tramway = 6 900 ft
Difference in elevation of ends of tramway = 1 866 − 350 = 1 516 ft.

Let Fig 27 represent CONTROLLING MACHINERY arrangement for this tramway. Calculation of t and required for ascending loads

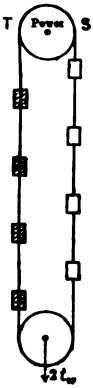

Fig 27. Power Machinery at Upper End

LOADED CARRIERS DESCEND

Loaded side; descending.

$$w = w_l = \frac{l+e}{d} + r = \frac{1\,220}{384} + 0.89 = 4.$$

$$t_l = 4.07 \times 1\,516 - 4.07 \times 6\,900 \times 0.$$
$$= 6\,170 - 562 = 5\,608$$
$$(T - S) = t_l - t_e = 5\,608 - 3$$

LOADED CARRIERS ASCEND

Empty side; descending.

$$w = w_e = \frac{e}{d} + r = 1.98$$

$$t_e = 1.98 \times 1\,516 - 1.98 \times 6\,900 \times 0.$$
$$= 3\,002 - 273 = 2\,729$$
$$(T - S) = t_l - t_e = 6\,732 - 2$$

In above case, for descending lo line, controlled by hand brakes, (stresses being too great for wood fi and $n = 2$; hence from Table 4, $e^{f\pi n} = 1.706$, which $S(e^{f\pi n} - 1)$, or $2\,333 = S\,(1.706 - 1)$; hence $S = 2\,3$ equals value of t_e; hence t_w might be zero if there power margin of 25%, new value of S is $4\,125$; subst gives $t_w = 4\,125 - 3\,275 = 850$ lb; therefore the should be 1 700 lb, which is reasonable.

To haul the same loads up the line, a grip sheave (Fig 29) would be necessary to develop required jaws have a ratio of 1 : 3; then $f = 3 \times 0.085$, $n = 2.228$ (Art 3). Substituting these values in Eq 31 $S(e^{f\pi n} - 1)$, or $4\,003 = S(2.228 - 1)$ and $S = 4\,003 \div 1$ which is greater than t_e. Hence, with no margin o sion weight of $2(3\,250 - 2\,729) = 1\,042$ lb is essen purposes. It will be well, however, to add 25% make up the increased tension on slack side by add sion weight.

Another combination occurs with CONTROLLING LOWER END of tramway (Fig 28). Then the tensio due to loading will be zero, and the only tension o driving sheave will be that given by tension weig sliding sheave; that is, $S = t_w$. Tension on taut si

$$T = (w_l - w_e)\,V \pm (w_l + w_e)\,fH + t_w,$$

the plus sign being for ascending loads, the minus f From these equations the force to control move $(T - S)$ can be determined. For ascending loads, p required, but for descending loads there are two c term may be the larger and the value of $(T - S)$ posi 2, on a gentle slope, second term may be the larger force is required to pull the loads down. With larg it is not practicable to place power machinery at l side must be obtained artificially, and by so doing t hibitively. Value of $(T - S)$ is substituted in Eq 3 and the value of S is determined. Since $S = t_w$ for t the required tension weight is known at once.

SIBLE AND SINGLE-ROPE TRAMWAYS

20. Reversible Tramways

on. These, sometimes called "jig-backs," consist of : 1. One or bles stretched at required tension from end to end. 2. Traction ving carriers. 3. One carrier on each track cable, moved to and on rope. 4. Station at each end for operating the machinery, and mping carriers. 5. Sometimes intermediate towers are used to k cable and traction rope. Towers are disadvantageous, as they to 1 000 ft per min, while without them carriers may be run at min. In operation, a carrier is filled at loading terminal, and runs terminal where it is dumped automatically. The machinery is l and carrier runs back on same cable. One man fills the car- rates the machinery.

n. Cost of erection and operation is low for small tonnages and es, but, owing to the reciprocating movement, limit of capacity is . Roughly, this limit occurs, with a 2-cable system, when product er hr multiplied by distance in feet = 20 000; that is, a tramway can handle 20 tons per hr, but one 2 000 ft long can handle only r. With a single track-cable, capacity is less than half the above.

es are seldom weighted, but are tautened by turnbuckles or wire-rope cable tension is judged by deflection of empty cable at center of span.

hen there are 2 track cables with 1 carrier on each, are clamped to trac hat one will be at loading terminal when the other is at discharge termi- is loading while the other is discharging. When loads are descending l often operate by gravity, like a gravity inclined plane. A reversible be operated with 1 track cable and 1 carrier. This is practically half a and always requires power.

rsible tramway is often used to transfer freight or passengers across a m. If there are no intermediate towers, the carrier hangers can be ex rom both sides of carriage, thus preventing carriers from jumping off each end, carriers stop just before terminal saddles are reached, for load- ging.

quired are: 1, plan and cross-sections, or contours, of volume to be the sections showing probable maximum depth of excavation; and elevation of discharge points; 3, kind, size, and weight per r cu ft, of material to be handled; 4, quantity to be handled in tons nature of power to be used.

load is sometimes governed by size of individual pieces or units. In strip- ally determined by quantity of loose material to be handled per hr, although gle blocks of stone may be the controlling factor. Net load equals tonnage d by number of loads that can be handled per hr.

load is made up of time to hoist, transport load, dump it, return the skip to ge connections to another load. Speed of hoisting and lowering may be as per min. Carriage can be hauled along cable at 1 000 to 1 500 ft per min, with l fall rope carriers, and at about 800 ft per min, with chain-spaced fall rope

nce time for one load $= \frac{2 \times \text{depth of pit}}{\text{hoisting speed}} + \frac{2 \times \text{distance hauled}}{\text{hauling speed}} + \frac{1}{2}$ min for dumping. Time to lower may be a little less than that required for hoisting. stance hauled may be taken as 80% of span; it can rarely exceed 90%, and is be over 70% for any length of time. Round trips often average 2 or 3 min.

able depends on load, span, and allowable deflection. In beginning is usual to allow a deflection of 0.05 of span, when load is at center, ition is covered by Eq 14. If size of cable be given, all quantities ember are known, and equation can be solved at once for deflection. is determined in terms of span, and size of cable is to be found, then unknown; but, from Table 2, t is about 7 000 times w, for safety factor t or w can be expressed in terms of the other quantity and equation iat quantity. It is usual, however, to substitute a value of w which is ely that of some similar installation, or that corresponds to typical is (Table 10 and 11). If this deflection seems reasonable, it is adopted, of towers are made to conform. If resulting heights of towers are too ger cable may be used and the increased tension then allowable will ction. Table 2 gives working tension for safety factor of 5, but if danger of cable being overloaded, the factor is often reduced to 4, ll deflection is desirable. Deflection of 0.05 of span was assumed for study only; on long spans deflection increases faster than span, due cable, hence deflection is often more than 0.05 of span; on short spans ay be taut and deflection less than 0.05 of span.

ad. Tension is maximum when load is at lowest point, and decreases as ither way. This variation in tension is unknown, hence the equations of ection, which involve tension, can not be used for determining deflection with us points. Path of load may be found approximately by assuming that the

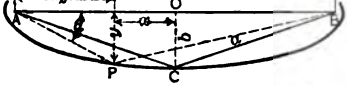

Fig 46. Path of Load on Cableway

A and B (Fig 46) are the foci Then lines $AC + CB$ equal s of ellipse, and the ellipse can be at center of span, and OC due to wt of cable and concen- center of span, then $OC = H$ semi-minor axis, while $CB =$ or axis of ellipse. The ordinates of any point P are x and y. The equation referred to its center is:

$$a^2y^2 + b^2x^2 = a^2b^2 \quad \text{or} \quad y^2 = b^2(a^2 - x^2) \div a^2 \tag{39}$$

d, from Fig 46, $a^2 = H^2 + (s^2 \div 4)$; hence, by substituting a series of values ponding values of y can be calculated and path of load determined for a ints.

If s be distance of load from end of span, the defl
gives slope of chord AP when load is near tower, ar

operate consists of: 1, engineman at hoister; 2, fireman, when an inde-
ler is used; 3, signalman, to give instructions to engineman for moving
ll block; 4, dumpman, to trip the carriers; 5, one or more hookmen in
tach fall block to the load and to give signal to hoist; 6, rigger or oiler.

not needed if there is a central steam plant, or for an electric hoister, but
power will partly offset his wages. Signalman usually stands in a balcony
ge, in view of both loading and dumping points; he communicates with
signals or telephone, giving orders in accord with signals of men at hook-
mping points. Sometimes the engine house can be located so that engine-
nto the pit, and receive signals direct. Dumpman is needed when dumping
or car, but not for automatic dumping. Hookman must be reliable, to
d securely, and start it properly from the bottom; he also sees that other
out of the way of the swinging carrier. Rigger inspects machinery, and oils
fall-block sheaves and tower-sheave bearings, at beginning and middle of
ring installation or repairs he has charge of the work.
he skips is chargeable to excavation, and not to cableway. It is often done
por; on Chicago Drainage Canal, 12 to 16 cu yd of rock were loaded per
r day. Loading is sometimes done with steam shovel or drag scraper.
e pit may serve to move the skips from loading point to a place where
icked up by the cableway.

26. Light Cableways

leways are used for trench work on sewers, subways, and similar
, shallow excavations (Fig 41). Towers are single A-bents, 25 to
nd the whole plant is designed for portability. After an excava-
n made for the length covered by one span, plant is moved ahead
section excavated. Spans are about 300 ft long and fall rope
usually dispensed with, as the empty bucket will keep hoisting
But if loads are being hoisted near center of span and are being
ower, a single fall rope carrier may be run out on track cable and
a chain dropped to the ground. It is set where it will not inter-
rriage, but where it will hold up center of hoisting rope when car-
ne tail tower. (Made by 9, Art 27.)

. Machinery for a light cableway for a net load of 2½ tons on a 300-ft
of: 1⅛-in main cable, of cast steel with 19 wires, with anchorage and take-

up fittings; 5/8-in hoisting and traversing ropes; wi
and 16-in sheaves; fall block with 16-in sheave;
dumping and self-righting tubs, 48 in wide by 45 in
hoist, cylinders 8¼-in diam by 10-in stroke, drum
drum 25-in diam by 26 in concave face; vertical tub
engine car with 10 by 16-ft timber platform, hou
wheels; 180 ft of 25-lb T rail for moving car; 2 tow
with 1-in galvanized steel guy ropes.

ng idlers have been used to a small reduce power consumption about ⅓ 4). Dust stops must be carefully o exclude grit; fine mineral dust ise speedily ruin the bearings.

nearly always of canvas and rubber, the canvas weighing 28 to 32 oz, cotton. The "friction," of rubber gum cement between plies, must uality to prevent separation of the plies. Testing a 1-in strip, cut by al knife-cut (wet knife with water) and peeled loose at the top, a pull of 16 to 20 lb should shear the strip, if of best quality, 10 to 14 lb and 7 to 8 lb for inferior. The carrying cover is usually $\frac{3}{16}$ in thick; gh for medium service; more than $\frac{3}{16}$ in is rarely used. The other in thick. Edges should be well molded and reinforced. Greatest e center, where the load is greatest and where the first fall from chutes s led to the thick-centered Robins belt (Fig 30), which incidentally increases lateral flexibility, with edge stiffness. An ordinary straight-ply belt will trough under its own wt, if 30 in wide or more. Long belts for a given tonnage are presenting more surface than shorter belts for same tonnage. When ded, belts wear better than if lightly loaded, as the bombardment e is lessened by keeping full load. (See Fig 38, 39.)

ick-centered Robins Belt

PICKING BELTS is about 30 ft per min; for GENERAL SERVICE, 350 o to 500 ft per min is ideal for lump materials. For fine granular er min has been used successfully, but is not advised; at 500 ft, a olves nearly 320 rev per min. Impact at deliveries increases as V^2 ad coming on at chutes also increases with speed.

riving should be of tough grey iron, with ribbed spokes, as the pull may be eccentric. Extra high crowns are desirable to keep belts centered. Con- nder double arms are advisable, also reinforced edges of rims to prevent ny good conveyers have only 3 in of driving pulley diam per ply of belt; ended for long belt life. Pulleys do not wear out, belts do. Tail-pulleys carrying less total tension. The snub or bend pulleys near drive should be s drivers. Troughing idlers are commonly 4, 5, 6, and 7 in diam, depending ortance of conveyer. Since greatest percentage of power lost is in turning n are preferable. Idlers with high rotative speed should be turned and bal- rs are best, resisting corrosion, and are worn through only by belts carrying t coke breeze. GUIDE IDLERS are unnecessary with good erection, and well- y are a safeguard against accidents which might cause belt to leave its trou

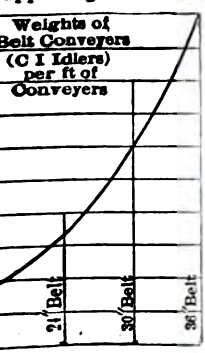
ts (Fig 50). Belt conveyer is light and compact, and, in estimating costs, supporting structure should be credited. Trippers weigh 800 to 4 000 lb.



Structures and housing. Most belt conveyers are exposed to the weather. Conveyers on trestles often have low corrugated steel wind shields, to prevent the empty belt from being blown off the idlers, and starting up in that condition. Many are covered with low dog-house structures, just large enough to enclose the conveyer, with a railed walk alongside and hinged roofs. Trusses under trippers should be counterbraced. Idlers are usually mounted on planks or channels, with a continuous deck between them, built in removable panels, to keep fines off the lower return belt, and from falling farther. Stiff cross-bracing is essential to keep belt in a straight line horizontally.

Grades should not exceed 20°, to prevent slow creep of the load on face of belt; 18° is better. A 27° grade will work, but steep angles lessen belt life. On tripper lines a depressed tail is desirable, to prevent the tripper from lifting against the loading chute and cutting it (Fig 51). The angle should be an 15°. When steep grade is unavoidable, wear can be reduced by deep and steady stream of rom loading chute.

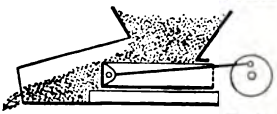

Fig 56. Dempcey's Plunger Feeder

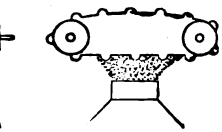
y can be calculated by displacement, main factor being breadth. Re- feeders, if made as shown with a back plate, are really stationary pusher feeders. The incline does not increase capacity, but lessens work.



57. Apron Feeder

Apron feeders (Art 2) make an excellent gate for ore (Wellman-Seaver-Morgan Co) and may be power-driven (Fig 57). No skirt-boards are used. Rotary plates, as in the Chal-

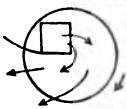


Fig 58. Action of Plate Feeder

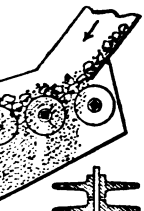
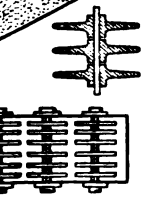
and Trump mixer, consist of circular plates, level or slightly h a plow. They will not sweep off theoretical volume, owing to slip backwards on the plate (Fig 58).





Stockwell Feeder

Revolving grizzlies were introduced by E. V. Stockwell, chief engr, Braden Copper Co (Fig 59). A single set or a series of rolls may be used. The C-I plates are tapered to prevent wedging of lumps, and are loosely fitted on a square shaft to aid in freeing lumps. With sticky materials, stationary finger bars between disks will clear them. The spaces drop out the fines to a by-pass chute.

Roll-feeders, introduced by Hoover & Mason for ore and limestone, have a single hollow roller with C-I spiders and plate barrel (Fig 60); they also serve as gates. They feed too unsteadily for conveyers, but are good for filling cars. Variable-throw feeders are also used.

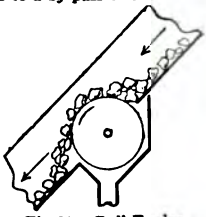


Fig 60. Roll Feeder

Gates of the undercut type are occasionally used driven by shafting and cranks or eccentrics. Cranks are preferable, giving and using less power.

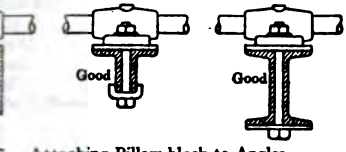
. Angle of teeth must not be too steep or the worm will overhaul; a gear 50 : 1 is good. Automatic solenoid grips are good, but expensive. In a e the utmost safety is desired, as over the roof of a power house, 2 stud-link laid along the tracks, anchored securely at each end, and with a bight carried ts or pocket sheaves. Links must be accurately pitched. Use a motor with gnet brake, and provide a screw post-brake for hand use in reserve. The thod is to use anchored wire ropes driven by geared windlasses. Tension tained in the ropes, as the drive is by friction. With a barom warning, there e to chain trucks to track and chock wheels.

10. Structures. Costs

upports receive the first shock, with small mass to absorb the blow; load and acceleration should be doubled when designing beams and connections. A descending empty carrier, suddenly arrested, may cause greater stress than the rising load plus acceleration. Large longitudinal stresses in conveyer supports, as from acceleration and retardation, often exist in addition to ction, requiring treatment as columns, and good cross-bracing. This in conveyers not driven at the head.



7. Attaching Pillow-block to Angles

ess often overlooked is due to the slewing of articulated spans. All spans uld be articulated, as it is impossible to drive the 2 ends alike; otherwise the will tear out. Spans supported on on the tower column caps require a lip them. This becomes a cross-bend- he horiz wind-truss system and upper s torsional stress on the supporting ng + and − stresses in columns, and esses in the column bracing. Mem- ten be calculated for deflection, not for cially for machinery supports. Pillow plates should not be bolted to legs of will deflect (Fig 67). On beams, use through-bolts to put stress into web, not g 68). Room for shims should be allowed on all structural work, to allow for inaccuracy in alinement. Engine bedplates and heavy pillow blocks on structural steel girders should have through-bolts to put tension directly into web, with ground-end stiffeners between chord angles to prevent rocking (Fig 69). Tension members should be bolted, not riveted, when connections are not in shear. Rivets in tension must be used in boiler bracing. However, many experiments show that rivets may cool in tension right up to the elastic limit; the longer the rivet, the greater the danger (see also Sec 43, Art 27). For machinery supports it is better to drill holes after erection to template, and use fitted bolts (tapered are better) for a driving fit, which will not work loose. Important bolts can rmly elastic by drilling a hole to reduce area of cross-sec in the body to that of on. Otherwise, bolt will fail in thread, as the rate of stretch is greater for a the lesser cross-sec. The pull on connection bolts is often twice as great as e member (Fig 70); there is a moment about the toe of each angle. Load

1. Definitions

ng, or concentration, is the mechanical separation of gangue, or worth-rom valuable minerals of an ore. A MINERAL (Sec 1) is an element, or a ound, in which the valuable substance is present in constant or nearly rtion. An ORE (Sec 2, Art 13) is a mixture of minerals, the valuable sub-present in indefinite proportion. An ore may contain several minerals me valuable metal, or different metals; or a single mineral yielding several s; it may also contain one or more gangue minerals.

this section, valuable minerals, before concentration, will be termed ue or useless minerals, WASTE. Crude ore is termed FEED. (The word t used here, because not distinctive.) Separated values will be termed and waste minerals, TAILING. In a 2-mineral separation, as quartz and n the galena concentrate and the quartz tailing there will usually be an roduct, MIDDLING, composed of "included grains" of concentrate and waste, p and too rich to discard. Successful treatment of middling is often the nd costly problem in concentration. In a 3- or 4-mineral separation, for a (sp gr 7.5), pyrite (sp gr 5), blende (sp gr 4) and quartz (sp gr 2.64), the contain not only "included grains," but also medium-weight minerals, ing the separation.

2. Principles of Ore Dressing

s of minerals which assist in separating values from waste are: ty, hardness, tenacity, fracture, aggregation, color and luster, adhe-ness," electric conductivity, magnetic permeability, decrepitation. hese are defined below.. For further details see Richards' "Ore

vity (Sec 1, Art 3) is of prime importance, since it affects the settling ticles in water, air, or other media. Of two particles having same size and erent sp gr, the heavier will settle the faster; and of two particles having t different size, the larger will settle the faster. Thus, the sp gr of galena hat of calcite being 2.713, galena is 7.5 ÷ 2.713 or 2.762 times as heavy as merged in water, the ratio of effective sp gr of galena and calcite would be .713 — 1) = 3.794; hence the facility, in most cases, of wet, as compared ntration. See Table 1 on opposite page.

luster assist in distinguishing minerals in hand picking. ADHESION en-ght gold to be taken from pulp or sands by amalgamation. GREASINESS, ON, or aversion to being wetted with water, is the key to flotation methods. DUCTIVITY is the basis of electrostatic processes. Good conductors are d with electricity, and are then repelled by the electric pole, the reverse be poor conductors. By this means pyrite can generally be separated from NETIC PERMEABILITY is the basis of magnetic separation; for example, ble magnetite from non-permeable quartz.

BREAKING AND CRUSHING

3. Breaking by Hammers

dges, or 2-hand hammers, are used for breaking large pieces of ore able to enter the rock-breaker jaws. Where high-grade values cleave ow-grade, hand picking (Art 14) may accompany this work. Sledges striking faces, with beveled edges or sharp edges, or a sharp pean o aid in cleaving. The pean may be parallel or at right angles to ights of sledges are from 10 to 16 lb, 10-lb being preferred for at high altitudes, 16-lb for hard rock, and 12-lb for average service. ge from 28 to 36 in, 34-in being a common length. SPALLING e 2-hand hammers, weighing 2 to 4 lb, for breaking moderate-size

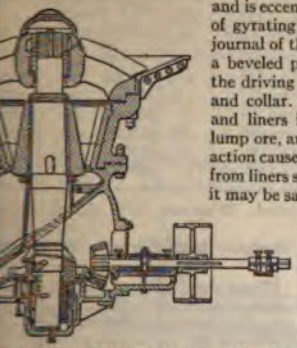
yratory breaker (Fig 3) crushes by gyrating a truncated conical end up) within a truncated conical ring die or ring of liners (small

ad spindle is pivoted at upper end, and is gyrated in a circle of small diam- end by a horizontal beveled gear. The spindle journal is in a long hub, and is eccentric to it by an amount equal to radius of gyrating circle. The outside of the hub is the journal of the bevel gear. This gear is driven by a beveled pinion on a horizontal shaft, to which the driving pulley is attached by a shearing pin and collar. The opening between crusher head and liners is large at the mouth, for receiving lump ore, and small at throat (9). The gyrating action causes breaker head to approach and recede from liners successively around the circle; whence it may be said that the gyratory breaker is crushing half the ore all the time, while the Blake and Dodge are crushing all the ore half the time. Moreover, the gyratory requires no flywheel.



n of Gates-McCully Gyratory Breaker

Adjustments. As the breaker head extends below the liners, wear is taken up by lifting crusher head. The Gates device for this was a vertical set-screw, and blocks or buttons aring of the shaft. The McCully improvement puts lock-nuts on upper end iminating considerable friction of spindle in the step-bearing, due to its liminishing the power required. The Gates style K breaker accomplishes a nut with split side and locking bolt.

l products. Like the Blake, the gyratory takes large sizes, 6 to ing them to 1 to 4 in. A large machine for coarse work may be 2 or 3 small machines for fine work. To receive lumps of the Gates gyratory needs about 3 times as much mill height as a jaw

(a) Machine has 2 openings, each of size stated.

yratory crusher. Gyratory is more efficient, mechanically; hence here large capacity is required. Wear and repairs cost more for To take feed in large chunks, jaw crusher is lighter, cheaper, and ch less mill height. Best arrangement for such condition would be crushers delivering to 1 gyratory, with another gyratory in reserve.

rather than chilled cast iron; manganese steel po
nary steel, in fact, is found more apt to become gr
iron is that it costs less; for the various steels, tha
may cost 2 to 4¢ per lb, cast steel 6¢, forged, ha
chrome or manganese steel 10¢ The question t
least cost per ton, taking into account labor of c
pages. ROLL FRAMES are best made in a comple
ing bearings, springs, etc, and 2 ends for stiffness
of mild steel or wrought iron, made extra heavy

Pillow blocks of fixed roll should be built true,
accurate alinement. This is done by springs, screws,
cheek bearing to help this, to which is sometimes add
ends of adjustment screws, causing the screws on both
amount. McFarlane has a sliding frame for moving
which guarantees parallel roll shafts. Krom has swin
shaft resting upon 2 parallel arms, keyed to a conn
bearing thus causing similar movement in the other.

Springs. The actual crushing force may no
to use springs giving much greater pressure, 15
size of rolls. Springs avoid damage when an

incur unequal crushing under ordinary operation. RIGID ROLLS Eng Wks) yield more uniform product, and can be protected by ed under a strong electro-magnet.

g mechanism. Slow-speed, geared rolls are still used to some ex- power being received by belt from a fast countershaft. Slow rota- nsmitted by gears to the fixed roll, from which long-tooth star gears e moving roll. Three pairs of star gears, graded in size, will serve a lls from maximum size when new to minimum size when worn out. m- and high-speed rolls a direct and a crossed belt make the simplest here it is desirable to have the power shaft near the rolls, an extra and large diam pulley are used on fixed roll, while a small belt and ve for the crossed belt for moving roll.

rolls. Width of face varies from 9 to 18 in, usually 14 or 16 in. ge from 12 to 42 in; sizes commonly used are 24, 26, 30, and 36 in. mill has rolls 72-in diam by 20-in face. The Utah Copper Co and mill both employ rolls of 54-in diameter.

Because of the great variation in diam of rolls, peripheral speed best measure for comparison. Speeds range from 30 to 40 ft per Cornish rolls, to 800 or 1 000 ft per min in modern high-speed rolls. believes average of modern coarse rolls is about 650 ft per min; eed fine rolls, 900 ft per min.

, ridges, corrugations, and pits. If rolls lap slightly over each unopposed edges wear less and bad flanges soon form. Circumfer- es and hollows are often formed on surface of rolls. Chilled shells, f of poor metal, may become pitted with cavities large enough to let ere drop through without being crushed. With close-fitting cheek s can do no crushing on their extreme ends, when crushing 1-in stuff, se both rolls become flanged at both ends.

ay be prevented, or cut away, by running with cheek plates offset from ends stance equal to the half-diameter of maximum grain in the feed. Flanges nd down by an emery block held against them by a heavy weight; or better, emery wheel may be used while roll is running slowly; or the roll may be the, with an emery wheel. If the rolls in a mill are uniform, new shells may fine crushing, shifting them to coarse rolls when surfaces are too rough for To secure uniform wear, rolls may be shifted every day; first lapping one he other. Side shifting may be done automatically; H. K. Burch has de- roll (made by Traylor & Co). J. S. Frazee (15) for dry fine crushing makes r than the other, so that 2 flanges form; by careful feeding this roll wears ghout its life. Badly pitted shells are best discarded.

. The following are all good: Gates stirrup feeder, Tulloch jerking- ndy Challenge, and the cylinder feeder. The feeder must prevent re, and distribute the ore evenly from side to side of rolls. Guide ometimes put into feed spout, to direct feed away from a low spot high spot on the shell.

feed. Angle of nip. Space between rolls. Size of feed rarely in (37 mm) diam, and a minimum of 1/12 in (2 mm) is rarely passed. e too large they cannot be nipped by the rolls. For quartz ores the one roll at point of contact with maximum grain of feed ore should gle not greater than 32° with the similar tangent of other roll. Fric- n roll and fragment will then be sufficient to draw in the fragment t. This angle is called ANGLE OF NIP. To secure it, diam of roll, een rolls, and diam of particle, must all be considered. Slippery e anthracite, graphite, and talc, need a smaller angle of nip.

With rapid-running rolls it may be well to r
because rock fragments are batted from one r
time to settle and give friction a chance to nip

Graded crushing. While rolls rank as the prod
tage can be enhanced by crushing in stages. For e
to 12 mm, the second from 12 to 6 mm, and the thi
screened out between the stages, the total product
than if all the crushing had been done in one oper
fines at each step, the total quantity of fines is reduc
excess of fines, rolls should not be required to reduce
diam.

Choke crushing. In some circumstances it is de
of ore to a fine size without regard to production o
used small rolls with 90° pyramids all over their surf
spaced ½ in between points of pyramids. These w
customary for free crushing or minimum fines, ore p
ing in greatly increased capacity.

Free crushing. This is the normal way of runni
rolls be imagined to be rolling out a ribbon of dough,
Assume rolls 15 in wide (1.25 ft), with peripheral sp
(0.0417 ft), and that broken quartz weighs 110 lb p
min, the theoretical crushing capacity is:
(650 × 1.25 × 0.0417 × 1 440 × 110) ÷ 2 000 =
mills, the amount actually crushed is only from ½0

Ratio of roll opening to trommel hole.
quite down to size of their opening. When the
the screen holes should be 1.25 times the wid
trommel oversize to a small amount.

Journal friction. If rolls are set in contact, with
the whole pressure may be on the journals, requir
overcome friction even when no crushing is being do
by the thickness of a sheet of paper, then the sprin
and acts on the journals only when the crushing pr
space between the rolls. By observing this precaut
avoided.

Power required by rolls is difficult to stat
with speed, size of feed, size of product, and h
mates by a builder of rolls are given in Table 1

Table 17. Size, Weight, Power, etc, of Rolls (17)

Weight, lb	Approx cost	Approx h p
xtra heavy, style A		
197 000	$9 000	55–135

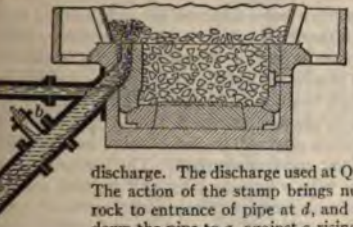
gear. It will crush 88 tons of rock per ton of coal
single-cylinder stamp, 20 in diam by 24 in stroke, crus
63 tons per ton of coal. Capacity, 500 to 600 tons of
loid per 24 hr, through 5/8-in mesh. ALLIS-CHALMER
with 24 by 24-in cylinder, ranks with the highest
stamps at Lake Superior. Capacity, 600 to 700 to
diam, and it is claimed to be as economical as the

ady running, and ease of repairs, although its capacity is less per ton of coal berg. The usual single cylinders at Lake Superior are 20 by 24 in. Leavitt hp on up stroke, 103 hp on down, total 146 hp. Allis-Chalmers stamp, nd 109 hp on down stroke, total, 171 hp.

ta. Rotation is by belt to pulley on stamp shaft between its stamp revolves once in about 6 strokes. It makes 90 to 100 24-in in; speed at instant of blow, 20 to 26 ft per sec. Approx weight of : shaft, 3 500 lb; shoe, 600 lb; piston rod and piston, 700 lb; total, b. Water used in stamping, about 55 tons per ton of rock.

The rock, which has passed through a 3-in grizzly, is fed from a chute. picks out nugget copper, wood, and sometimes waste rock, and regulates the feed. A tell-tale bell, struck by a tappet on stamp shaft, rings if stamp drops too far, owing to mortar being too empty. The crushed material passes through screens, much of the nugget copper going through a special mortar discharge. The discharge used at Quincy mill is shown in Fig 8. The action of the stamp brings nugget copper and pieces of rock to entrance of pipe at *d*, and the nuggets find their way down the pipe to *a*, against a rising current of water too swift to allow waste to settle. Valve at *b* must be closed when nuggets are discharged from pipe at *a* (21).



y Mortar (21)

Clean-up. Stamp shoe wears out in 2½ days on conglomerate, and 6 to 12 days on amygdaloid. Stamp is then stopped, front screen removed, shims driven out, old shoe replaced by a new one, shims replaced, screen, staves, die, and other parts frame replaced, and the stamp restarted. The residue is cleaned up and n a "bull jig."

9. Huntington Mill

a fine crusher of the roller type, the rollers having vertical axles sus- flexible joints from a central spider, thus allowing them to swing out gal force against a ring die in rim of pan. The ore, fed with water, is ainst the die, crushed by the rollers, and can not leave the mill until gh to pass through the screen. Like the Chili mill, the Huntington y adapted to recrushing middlings. It has to some extent replaced mill for gold ores, but in preparing for amalgamation it is inferior to it does not burnish the gold particles so well.

tion. The pan has a central hollow post, through which a vertical shaft wer through bevel gears to rollers. Above the ring die the rim carries screens ree-quarters of the circumference, and above the screen the sides rise to height . The feed spout, which is level with the screens, occupies about one-quarter Around the screens is a ring launder and spout for discharging pulp. The have T-shaped tops and bearings, which allow the rollers to swing freely nst the die. The centrifugal crushing force increases with speed of rotation. nd die have replaceable shells. Roller shells wear from 1.5 in to 0.5 in; die 2 in to 0.75 in. Roller shells of Latrobe and Midvale steel last an average die rings, 75 days.

screens. Though the mill can crush coarser sizes, it does best work on feed 6.3 mm) maximum grains. Horizontal-slot screens are better than those or square holes, because of the tangential path of particles passing through. screen has 1.5 times the percentage area of opening of the punched slot; orded 14-day test, the woven slot did poorer work than the punched screen, .43 tons per 24 hr, against 73.57 tons from the punched slot. Difference was ding" of the woven screen.

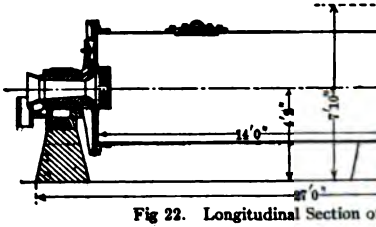

Fig 22. Longitudinal Section o

larger, to cause pulp to flow in that direction (somet
ing spiral, for removing the pulp; in which case a s
is operated by a driving pinion, engaging with a t
Cylinder is lined with silex bricks, or with flint pebb

al iron ribs, or with steel or chilled-iron blocks. It is charged with loose flint ebbles (lumps of hard, tough ore are sometimes used), the cylinder being kept pebbles as possible, without their discharging with the pulp. New pebbles are day to make up for wear. Grinding is effected by: falling of the pebbles as es, crushing between pebbles, and crushing between pebbles and lining.

es and lining. Greenland flints have proved best; cost $20 per ton; 1 ebbles will crush 1 ton of sand. Cheaper pebbles are also used, of which will crush 1 ton of sand. From ½ to 1 lb of liners will do the same. charge for a mill 5 ft diam by 14 ft long is 4 tons of pebbles, costing 4 per ton, according to quality. Cost of silex lining varies, with quality, or $1 per sq ft, when 2.5 in thick, to $1.60 per sq ft, when 4 in thick. practice shows a service of 8 months on 2.5-in lining, 1 year on 4-in Price of chrome-steel lining for ball mills is 6¾¢ per lb.

mill feed is usually 8-mesh and finer, but a size of not over 0.02 in t results. For cyanide process, Argall gives this rule: Breaker to 2 in; .75 in; rolls to 0.24 in; rolls to 0.06 in; grinding pan to 0.02 in; tube- 0.0025 in (200 mesh). Fineness of tube-mill crushing is largely con- y rate of feed; the faster the feed, the coarser the product. Highest is attained on pulp containing about 39% water.

and power required. A 36-in tube-mill makes 36 rev per min; rev; 60-in, 28 rev; 72-in, 25 rev. Power varies with size of mill and f pebbles used. Davidson gives the rule: Hp = 0.15 × (volume of in cu ft); and suitable weight of pebbles in lb = 44 × (inside volume ill in cu ft). Experience with the Hardinge mill in Lake Superior mills a saving of about 10% in cost of installing power transmission by use lual motors, as against line-shaft method (107).

y of pulp. The ordinary overflow discharge has the disadvantage, with the spiral lift discharge, that the product delivered is classified; ts maximum grains of valuable heavy mineral are smaller than the grains of light waste, because they are of equal settling velocity. shows results at Kalgoorlie, where a classifier returned coarse ma- ube-mill for very fine grinding.

Table 34. Screen Test of Tube-mill Product, Kalgoorlie (35)
